ais.to.DeponsShips Convert ship tracks to DeponsShips object

Description

Index

Convert Automatic Identification System (AIS) data for ships to ship track objects. This is done by cropping one or more ship tracks to the extent of a landscape and converting the data to a DeponsShips-class object. If the AIS data does not include ship positions recorded in half-hour steps, the tracks are interpolated to make objects suitable for use in DEPONS.

Usage

ais.to.DeponsShips(data, landsc, title = "NA", ...)

Arguments

| data | data.frame with ship positions and the times at which the positions were recorded. Must contain the columns 'id', 'time' (of the form " type, character), 'length' (ship length, meters), 'x', and 'y' (position, meters/UTM). |
|--------|--|
| landsc | A DeponsRaster object corresponding to the landscape that the ships move in. It is assumed that the spatial projection of the ship positions corresponds to that of the DeponsRaster object |
| title | Title of the output object |
| | Optional parameters, including 'startday' and 'endday' (" from 'data'. If startday = endday the output object will contain up to 49 positions from the selected date for each vessel track. |

Value

Returns a DeponsShips object containing one or more ships assigned to each of the routes in the object. All ships on a particular route move at the same speed along the route. The routes are defined by x and y coordinates based on the same coordinate reference system as the landscape they are located in. The speed that ships use after reaching a particular position (a particular 'virtual buoy') is calculated from the distance to the following position, and the time it takes reaching that position. If speed is included in the input AIS data, this is NOT used. The routes include one position per half-hour time step, corresponding to the default time step used in the DEPONS model. If input data does not include one position per half hour, new positions are generated using linear interpolation. If the input data contains many positions in a particular half-hour interval, only the positions closest to the half-hour interval are used. The routes contain information about the number of half-hour intervals were ships 'pause' at a particular location, e.g. in a port. These are calculated based on the input AIS data.

See Also

aisdata for an example of data that can be used as input to ais.to.DeponsShips and interpolate.ais.data interpolation of tracks. See write.DeponsShips for conversion of DeponsShips objects to json-files to be used in DEPONS. Use routes, ships, and title for inspection/modification of the ship tracks.

Examples

```
data(aisdata)
plot(aisdata$x, aisdata$y, type="n", asp=1)
ids <- sort(unique(aisdata$id))
my.colors <- heat.colors(length(ids))
for (i in 1:length(ids)) {
    id <- ids[i]
    points(aisdata$x[aisdata$id==id], aisdata$y[aisdata$id==id],
        cex=0.6, col=my.colors[i])
}</pre>
```

```
data(bathymetry)
plot(bathymetry, add=TRUE)
depons.ais <- ais.to.DeponsShips(aisdata, bathymetry)</pre>
the.routes <- routes(depons.ais)</pre>
for (i in 1:length(ids)) {
points(the.routes[[i]]$x, the.routes[[i]]$y,
        cex=0.6, pch=16, col=my.colors[i])
}
depons.ais <- ais.to.DeponsShips(aisdata, bathymetry,</pre>
   startday="2015-12-20", endday="2015-12-20")
routes(depons.ais)
aisdata2 <- aisdata
aisdata2$time <- format(as.POSIXct(aisdata$time)+300)</pre>
depons.ais2 <- ais.to.DeponsShips(aisdata2, bathymetry,</pre>
                                 startday="2015-12-20", endday="2015-12-21")
routes(depons.ais2)
```

aisdata

Position for three ships in the inner Danish waters

Description

Automatic identification system (AIS) data for three ships in Kattegat and the Western Baltic from 20 Dec 2015. The data set includes the variables id (the Maritime Mobile Service Identity number), time, speed (in knots), type, length (in metres), x and y (which provide the coordinates of the ship at a given time. The coordinates use the UTM zone 32 projection (CRS = "+proj=utm +zone=32 +units=m +no_defs +datum=WGS84").

Format

data.frame

bathymetry

Bathymetry of the Kattegat area

Description

The standard bathymetry file for Kattegat which is used in DEPONS simulations. It is based on a raster file with 1000 rows and 600 columns where each grid cell corresponds to 400 m x 400 m. Cells on land are assigned a missing data value of -9999.

The Kattegat landscapes use the UTM zone 32 projection, (EPSG:32632) as in the study by Nabe-Nielsen et al (2014). The corresponding proj4string is "+proj=utm +zone=32 +datum=WGS84 +units=m +no_defs" (see https://epsg.io/32632).

Format

DeponsRaster

See Also

DeponsRaster-class

bbox

Get bbox from Depons* object

Description

Retrieves spatial bounding box from object. If a Depons* object is a DeponsTrack object containing multiple track, the box bounds all tracks.

Usage

S4 method for signature 'DeponsRaster'
bbox(obj)

S4 method for signature 'DeponsTrack'
bbox(obj)

Arguments

obj DeponsRaster or DeponsTrack object

Value

Returns a matrix defining the northern, southern, eastern and western boundary of a DeponsRaster object or of one or more DeponsTrack objects.

See Also

make.clip.poly

coastline

Description

An object of class SpatialPolygonsDataFrame showing the coastline of the North Sea, Kattegat, and the Western Baltic. The map projection used is ETRS89 – EPSG:3035 projection as for the North Sea raster files used by DEPONS. The corresponding proj4string is "+proj=laea +lat_0=52 +lon_0=10 +x_0=4321000 +y_0=3210000 +datum=WGS84 +units=m +no_defs".

Format

SpatialPolygonsDataFrame

crs

Get or set map projection in Depons* objects

Description

Get or set the map projection (also known as coordinate reference system, crs) of DeponsRaster and DeponsTrack objects. For sp objects the text string defining the crs is called the proj4string.

Usage

```
## S4 method for signature 'DeponsTrack'
crs(x)
## S4 method for signature 'DeponsShips'
crs(x)
## S4 method for signature 'DeponsRaster'
crs(x)
## S4 replacement method for signature 'DeponsTrack'
crs(x) <- value
## S4 replacement method for signature 'DeponsShips'
crs(x) <- value
## S4 replacement method for signature 'DeponsRaster'
crs(x) <- value</pre>
```

| Х | Object of class class DeponsRaster, DeponsShips or DeponsTrack |
|-------|--|
| value | proj4string identifying the map projection |

Description

Methods for analyzing population dynamics and movement tracks simulated using the DEPONS model (v.3.0; http://www.depons.eu), for manipulating input raster files, shipping routes and for analyzing sound propagated from ships.

The classes used in DEPONS2R include:

- DeponsTrack movement tracks, read from "RandomPorpoise.XXX.csv" files
- DeponsDyn population dynamics data, from "Statistics.XXX.csv" files
- DeponsBlockdyn data from "PorpoisePerBlock.XXX.csv" files
- DeponsShips data from "ships.json" files or from AIS data

Here the DeponsDyn data include both changes in population size and energetics through time for the entire landscape, whereas DeponsBlockdyn data include variations in population size in different parts (or 'blocks') of the landscape. XXX is the date and time when the simulation was finished.

DeponsBlockdyn-class DeponsBlockdyn-class

Description

Stores objects containing population size for different parts of the landscape (i.e. different 'blocks')

Details

The dyn slot contains a data frame with the columns 'tick', which indicates the number of halfhourly time steps since the start of the simulation; a column 'block' indicating the region of the landscape where animals were counted, a 'count' column with the number of animals in that block and tick. The 'real.time' column shows the real-world equivalent to 'tick, i.e. the time that has passed since 'startday'.

Slots

title Character. Name of the object or simulation

- landscape Character. Identifier for the landscape used in the DEPONS simulations. The landscapes 'DanTysk', 'Gemini', 'Kattegat', 'North Sea', 'Homogeneous', and 'User defined' are distributed with the DEPONS model.
- simtime POSIX1t object with the date and time when the simulation was finished. This is read from the name of the imput file.
- startday POSIXIt object with the first day of the simulation, i.e. the first day in the period that the simulations are intended to represent in the real world.
- dyn Data frame with simulation output.

DeponsBlockdyn-objects are usually read in from csv files produced during DEPONS simulations. These files are named 'PorpoisePerBlock.XXX.csv', where XXX indicates the date and time when the simulation was finished.

See Also

plot.DeponsBlockdyn and read.DeponsBlockdyn.

Examples

a.DeponsBlockdyn <- new("DeponsBlockdyn")</pre>

a.DeponsBlockdyn

DeponsDyn-class DeponsDyn-class

Description

Stores objects containing population dynamics output and energetic output simulated using the DEPONS model.

Details

The following columns are included in the simulation output data frame: 'tick', which indicates the number of half-hourly time steps since the start of the simulation; 'count', which indicates the population size at a given time; 'anim.e', showing the average amount of energy stored by simulated animals; 'lands.e', which shows the total amount of energy in the landscape, and 'real.time' which shows the time relative to 'startday'.

Slots

title Character. Name of the object or simulation

- landscape Character. Identifier for the landscape used in the DEPONS simulations. The landscapes 'DanTysk', 'Gemini', 'Kattegat', 'North Sea', 'Homogeneous', and 'User defined' are distributed with the DEPONS model.
- simtime POSIX1t object with the date and time when the simulation was finished. This is read from the name of the imput file.
- startday POSIXIt object with the first day of the simulation, i.e. the first day in the period that the simulations are intended to represent in the real world.
- dyn Data frame with simulation output.

Note

DeponsDyn-objects are usually read in from csv files produced during DEPONS simulations. These files are named 'Statistics.XXX.csv', where XXX indicates the date and time when the simulation was finished.

DeponsRaster-class

See Also

plot.DeponsDyn and read.DeponsDyn.

Examples

```
a.DeponsDyn <- new("DeponsDyn")
a.DeponsDyn</pre>
```

DeponsRaster-class DeponsRaster-class

Description

Stores objects containing raster landscapes used as input in DEPONS simulations.

Slots

- type Character. Identifies the kind of data stored in the raster; should be 'food', 'patches', bathymetry', 'dtc', 'salinity', 'blocks' or 'NA'.
- landscape Character Identifier for the landscape used in the DEPONS simulations. The landscapes 'DanTysk', 'Gemini', 'Kattegat', 'North Sea', 'Homogeneous', and 'User defined' are distributed with the DEPONS model.
- crs Object of class "CRS", i.e. the coordinate reference system. This is provided as a proj4string text string.
- header Data frame with data on number of columns and rows in the input raster, the coordinates of the lower left corner, the size of each grid cell and the integer value used to represent missing data.
- ext Data frame with the extent of the landscape.
- data The actual data values for each of the grid cells.

Note

DeponsRaster-objects are typically read in from ascii raster files that have been used for DEPONS simulations.

See Also

plot.DeponsRaster, read.DeponsRaster and make.blocksraster.bathymetry is an example of a DeponsRaster-object.

Examples

```
a.deponsraster <- new("DeponsRaster")
a.deponsraster</pre>
```

DeponsShips-class DeponsShips-class

Description

Objects containing ship routes and ships

Methods for manipulating, plotting and analyzing ship routes and ship agents used in DEPONS simulations.

Slots

title Name of the object (character)

landscape Name of the landscape that the ships occur in (character)

- crs CRS object providing the coordinate reference system used; see CRS for details
- routes data.frame geographic positions of the 'virtual buoys' that define one or more ship routes that ship agents follow, and the speed that the ships should use when following this route. They also provide information about how long ships should use speed zero when reaching a specific buoy ('i.e. 'pause', measured in minutes). Can be extracted using the routes function.
- ships data.frame defining each of the ships occurring in DEPONS simulations, and the routes they occur on. The data frame includes the variables 'name', 'type', 'length', and 'route'. Info can be extracted using the ships function.

See Also

plot.DeponsShips, and read.DeponsShips

Examples

```
data(shipdata)
ships(shipdata)[1:10,]
routes(shipdata)
plot(shipdata, col=c("red", "purple", "blue"))
```

DeponsTrack-class DeponsTrack-class

Description

Stores objects containing animal movement tracks simulated using the DEPONS model Classes for manipulating and plotting movement tracks generated with DEPONS.

Slots

title Name of the object (character)

landscape Name of the object (character)

- simtime POSIXIt object with the date and time when the simulation was finished. This is read from the name of the imput file.
- crs CRS object providing the coordinate reference system used; see st_crs for details

tracks Listwith one or more tracks, each stored as a SpatialPointsDataFrame object)

See Also

plot.DeponsTrack and read.DeponsTrack

dyn

Extract population dynamics from objects

Description

Extract population dynamics from objects

Usage

S4 method for signature 'DeponsDyn'
dyn(x)

S4 method for signature 'DeponsBlockdyn'
dyn(x)

Arguments ×

Object of class DeponsBlockdyn.

get.latest.sim Get name of newest file

Description

Returns the name of the newest simulation output of a particular type within the specified directory. The date and time are extracted from the file name.

Usage

get.latest.sim(type = "dyn", dir)

Arguments

| type | Type of simulation output to check; can be one of: "dyn" (for looking in "Statis- tics.XX.csv" files), "blockdyn" (for looking in "PorpoisePerBlock.XX.csv" files) "track" (for looking in "RandomPorpoise.XX.csv" files). |
|------|--|
| dir | Directory to look for simulation output in (character string) |

Value

character string with the name of the most recent simulation output file.

See Also

read.DeponsBlockdyn for example.

get.simtime

Get simulation date

Description

Returns the date and time when a specific simulation was finished, obtained from the date stored as part of the file name. The date format is system dependent, but the function attemts to extract the data assuming that either the English or the local language is used. (a POSIX1t object)

Usage

get.simtime(fname = NULL, tz = "GMT")

Arguments

fname Character string with name of the file to extract the simulation date from, including the path

tz Time zone

Value

Returns a POSIX1t object

See Also

get.latest.sim

Description

Interpolates ship movement tracks obtained from Automatic Identification System (AIS) data to obtain exactly one position per 30 minutes. The first and last position in the original track are omitted unless minutes = 0 or 30 and seconds = 0.

Usage

```
interpolate.ais.data(aisdata)
```

Arguments

aisdata Data frame including the columns 'id' (ship identifier), 'time' (text string readable by as.POSIXct), 'x' and 'y' (recorded ship position, unit: meters), and potentially additional columns

Value

Returns a data frame with the same columns as the input data

See Also

read.DeponsShips

Examples

landscape<-

Description

Get or set the landscape name

Get or set the landscape name

Usage

```
## S4 replacement method for signature 'DeponsTrack'
landscape(x) <- value</pre>
```

S4 method for signature 'DeponsTrack'
landscape(x)

S4 replacement method for signature 'DeponsDyn'
landscape(x) <- value</pre>

```
## S4 method for signature 'DeponsDyn'
landscape(x)
```

S4 replacement method for signature 'DeponsBlockdyn'
landscape(x) <- value</pre>

```
## S4 method for signature 'DeponsBlockdyn'
landscape(x)
```

Arguments

| х | Object of class DeponsBlockdyn. |
|-------|-----------------------------------|
| value | Name of the landscape (character) |

make.blocksraster Makes new file with blocks

Description

Produces a DeponsRaster object of type='blocks' for use in DEPONS simulations. This allows animals to be counted within specific regions (blocks) of the landscape during the simulation. The new blocks can be specified as either matrices or SpatialPolygons objects. For matrices, the blocks are defined as the smallest rectangle that includes all the specified positions.

make.blocksraster

Usage

```
## S4 method for signature 'DeponsRaster'
make.blocksraster(
   template,
   blocks = NA,
   blockvals = NULL,
   NAvalue = -9999,
   plot = FALSE,
   fname = NULL,
   overwrite = FALSE
```

```
)
```

Arguments

| template | DeponsRaster object used as template for new blocks file |
|-----------|---|
| blocks | list of areas to be used for new blocks. Each item in 'blocks' should be a matrix (with two columns, corresponding to x- and y-coordinates) or a SpatialPolygons object |
| blockvals | Vector of integer values defining the labels of the new blocks. The first value de- fines the background value, so the length of 'blockvals' should equal the number of blocks plus 1 |
| NAvalue | Value used for missing data in the output object |
| plot | If TRUE, the raster block is plotted |
| fname | Name of the output raster file (character string ending with '.asc'). No file is written to disk if fname is not provided. |
| overwrite | Whether to replace existing file. |

Value

RasterLayer object defining different subregions of the landscape where animals should be counted.

Note

The blocks file should not be modified when running DEPONS simulations using the 'Kattegat' landscape. In this landscape the simulated animals use the blocks file for navigation. Also note that blocks are added to the new blocks raster in the order they are file in the order in which they are listed in 'blocks', so the order mattes if the blocks overlap.

Examples

#Load file to use as template for new blocks file data("bathymetry") # Make list of blocks to create new.blocks <- list() x <- runif(8, 70000, 760000) y <- runif(8, 6200000, 6300000) new.blocks[[1]] <- cbind(x,y)</pre>

```
x <- c(600000, 635000, 670000, 635000)
y <- c(6150000, 6200000, 6150000, 6100000)
library(sp)
srl <- list(Polygon(cbind(x,y)))
Srl <- list(Polygons(srl, ID=as.vector("p")))
new.blocks[[2]] <- SpatialPolygons(Srl, proj4string=crs(bathymetry))
make.blocksraster(bathymetry, new.blocks, plot=TRUE)
points(new.blocks[[1]])
plot(new.blocks[[2]], add=TRUE)
the.dir <- tempdir()
make.blocksraster(bathymetry, new.blocks, fname=paste0(the.dir, "/test.asc"))
```

make.clip.poly Make clipping polygon from bbox

Description

Makes a polygon from a bounding box to use for clipping the coastline, or other SpatialPolygons objects

Usage

S4 method for signature 'matrix'
make.clip.poly(bbox, crs)

Arguments

| bbox | 2x2 matrix |
|------|--|
| crs | CRS object defining the projection of the SpatialPolygons object to be clipped |

Value

SpatialPolygons object

See Also

bbox for creation of bbox matrix from DeponsRaster

Examples

```
data(bathymetry)
bbox <- cbind("min"=c(549517, 6155000), "max"=c(636000, 6210000))
rownames(bbox) <- c("x", "y")
clip.poly <- make.clip.poly(bbox, crs(bathymetry))</pre>
```

16

make.windfarms

Description

Produce a hypothetical wind farm construction scenario, specifying the position and timing of individual piling events, as well as the sound source level. All wind farms are assumed to consist of the same number of turbines, laid out in a rectangular grid. The start and end tick (i.e. the number of half-hour intervals since simulation start) is generated based on provided values for the time it required for each piling and the time between piling events.

Usage

```
make.windfarms(
 area.file,
 area.def,
 n.wf,
 n.turb,
  turb.dist,
 min.wf.dist,
  impact,
  constr.start,
  constr.end,
  constr.time,
  constr.break,
 iterate = 10000,
 verbose = FALSE,
 wf.coords = "random"
)
```

| area.file | Name of the raster file specifying where the wind farms should be constructed. |
|--------------|---|
| area.def | Value in area.file for the areas were wind farms can be located |
| n.wf | Number of wind farms to construct |
| n.turb | Total number of turbines to construct |
| turb.dist | Distance between turbines within a wind farm (meters) |
| min.wf.dist | Minimum distance between wind farms (meters) |
| impact | Sound source level (dB); sound emitted from turbines during construction, i.e. from tickStart to tickEnd (including both start and end) |
| constr.start | The tick at which construction of the first turbine starts. |
| constr.end | The tick at which construction of the very last turbine in the last wind farm ends. |
| constr.time | The time it takes to construct a single wind turbine (number of ticks). |

| constr.break | Break between individual pilings within a wind farm, counted in number of half-hour 'ticks'. |
|--------------|--|
| iterate | Number of times to try finding a spot for a new wind farm that is sufficiently far from the nearest neighbouring wind farm (>min.wf.dist). The number also defines the number of random positions to search through. |
| verbose | Logical; whether messages should be printed to console. |
| wf.coords | Possible location of the south-western corner of the wind farms. Defaults to the text "random", but can also be a data frame with coordinates in the columns x and y. |

Value

data.frame specifying the position of each turbine in a wind farm, along with the start time and end time for pile driving of the turbine foundation and the sound source level during pile driving. Can be exported as a text file and used for controlling DEPONS simulations.

Note

The parameters constr.start, constr.end, constr.time, and constr.break are truncated to nearest integer value. Construction of wind farms starts in WF001 at tick constr.start. Each turbine foundation is piled over a period of constr.time, followed by a noise-free period of constr.break. Several pile driving operations may take place at the same time, to ensure that the last piling ends before constr.end.

plot,DeponsBlockdyn,missing-method Plot a DeponsBlockdyn object

Description

Plot population dynamics simulated with DEPONS

Usage

```
## S4 method for signature 'DeponsBlockdyn,missing'
plot(x, y, dilute = 5, ...)
```

| х | DeponsBlockdyn object |
|--------|---|
| у | Not used |
| dilute | Integer. Plot only one in every 'dilute' values. Defaults to 5, which yields a plot of the first simulated value and one in every five of the following values. |
| | Optional plotting parameters |

Value

data.frame listing blocks where no animals were counted (returned invisibly)

Note

The function returns a data frame with numbers of blocks with no agents.

Examples

```
data("porpoisebdyn")
my.col <- c("red", "darkgreen", "orange")
plot(porpoisebdyn, col=my.col)
legend("bottomright", bty="n", fill=my.col, legend=paste("Block", 0:2))
# Show all data points for small range of x-values
plot(porpoisebdyn, xlim=c(1950, 2050), ylim=c(4850, 5050), type="p", dilute=1, col=my.col)</pre>
```

Description

Plot population dynamics simulated with DEPONS

Usage

```
## S4 method for signature 'DeponsDyn,missing'
plot(x, y, dilute = 5, plot.energy = TRUE, plot.legend = TRUE, ...)
```

| х | DeponsDyn object |
|-------------|---|
| У | Not used |
| dilute | Integer. Plot only one in every 'dilute' values. Defaults to 5, which yields a plot of the first simulated value and one in every five of the following values. |
| plot.energy | If set to TRUE it plots the amount of energy stored in simulated and in the landscape in addition to the population count |
| plot.legend | If set to TRUE, a legend is plotted |
| | Optional plotting parameters |

Examples

data("porpoisedyn")

```
# Plot for specific range of years
rg <- c(as.POSIXlt("2011-01-01"), as.POSIXlt("2018-12-31"))
plot(porpoisedyn, xlim=as.POSIXct(rg), plot.energy=TRUE)
## Not run:
# Read data from default DEPONS simulation directory:
sim.dir <- "/Applications/DEPONS 2.1/DEPONS"
new.sim.name <- get.latest.sim(dir=sim.dir)
new.sim.out <- read.DeponsDyn(fname=paste(sim.dir, new.sim.name, sep="/"))
plot(new.sim.out)
```

End(Not run)

plot, DeponsRaster, ANY-method Plot a DeponsRaster object

Description

Plot the values in a DeponsRaster object. Porpoisetracks or other kinds of lines, poits etc. can be drawn on top of the plot by adding

Usage

S4 method for signature 'DeponsRaster,ANY'
plot(x, y, col, trackToPlot = 1, ...)

Arguments

| х | DeponsRaster object |
|-------------|--|
| У | A DeponsTrack object or missing |
| col | A color palette, i.e. a vector of n contiguous colors. Reasonable defaults are provided. |
| trackToPlot | Integer indicating which track to plot if the DeponsTrack object contains more than one track. Ignored if y is missing |
| | Other optional plotting parameters, including 'axes', 'legend', and 'main'. |

Value

No return value, called for side effects

See Also

See method for plot in the raster package for plotting parameters and plot.DeponsTrack for plotting of DeponsRasters cropped to the extent of tracks.

20

Description

Plot the tracks that ship agents move along in DEPONS.

Usage

```
## S4 method for signature 'DeponsShips,missing'
plot(x, y, ...)
```

Arguments

| x | DeponsShips object |
|---|--|
| У | Not used |
| | Optional plotting parameters, including 'col', 'main', 'add.legend', and 'legend.xy' (defaults to 'topright' when add.legend=TRUE) |

Value

No return value, called for side effects

Examples

```
data(shipdata)
plot(shipdata, col=c("red", "green", "blue"))
```

```
# convert route coordinate units from 'grid squares' to UTM
data(bathymetry)
out <- summary(bathymetry)</pre>
left <- out[[4]][1]</pre>
bottom <- out[[4]][2]</pre>
for (i in 1:3) {
    newroute <- shipdata@routes[[2]][[i]]*400</pre>
    newroute$x <- newroute$x + as.numeric(left)</pre>
    newroute$y <- newroute$y + as.numeric(bottom)</pre>
    shipdata@routes[[2]][[i]] <- newroute</pre>
    }
# Reproject coastline and clip to size of Kattegat landscape
library(sp)
data(bathymetry)
data(coastline)
coastline2 <- spTransform(coastline, crs(bathymetry))</pre>
```

```
clip.poly <- make.clip.poly(bbox, crs(bathymetry))
plot(shipdata, col=c("red", "green", "blue"), add=TRUE, add.legend=TRUE)
plot(clip.poly, add=TRUE)</pre>
```

Description

Plot the coordinates in a movement track simulated with DEPONS.

Usage

S4 method for signature 'DeponsTrack,missing'
plot(x, y, trackToPlot = 1, add = FALSE, ...)

Arguments

| х | DeponsTrack object |
|-------------|---|
| У | Not used |
| trackToPlot | Integer; indicates which track to plot if there is more than one track in the object. Defaults to 1 |
| add | Logical, whether to add the track to an existing plot one animal was tracked during the simulation. |
| | Optional plotting parameters |

Value

No return value, called for side effects

Examples

```
data(porpoisetrack)
data("porpoisetrack")
plot(porpoisetrack)
```

22

porpoisebdyn

Description

An object of class DeponsBlockdyn with output from a DEPONS simulation based on the North Sea landscape, using a landscape divided into two blocks. Numbers of animals are counted per block.

Format

DeponsBlockdyn

See Also

DeponsBlockdyn-class, porpoisedyn

porpoisedyn

Simulated porpoise population dynamics

Description

An object of class DeponsDyn with output from a DEPONS simulation based on the Kattegat landscape, assuming that the simulation represents the period 2010-01-01 onward in the real world. Number of animals and energy availability is recorded for the entire landscape.

Format

DeponsDyn

See Also

DeponsDyn-class, porpoisebdyn

porpoisetrack

Description

An object with five elements: title, landscape, simtime, crs, and tracks. The crs stores information about the map projection used ("+proj=utm +zone=32 +datum=WGS84 +units=m +no_defs"). The tracks element is a list of objects of class SpatialPointsDataFrame, each ofwhich corresponds to one simulated animal. simtime is the simulation date.

Format

DeponsTrack

See Also

DeponsTrack-class

read.DeponsBlockdyn Reading simulated population count for blocks

Description

Function for reading DEPONS simulation output with number of animals per block for each time step.

Usage

```
read.DeponsBlockdyn(
  fname,
  title = "NA",
  landscape = "NA",
  simtime = "NA",
  startday = "NA"
)
```

| fname | Name of the file (character) that contains movement data generated by DE- PONS. The name includes the path to the directory if this is not the current working directory. |
|-----------|---|
| title | Optional character string giving name of simulation |
| landscape | The landscape used in the simulation |
| simtime | Optional text string with date of simulation (format: yyyy-mm-dd). If not pro- vided this is obtained from name of input file |
| startday | The start of the period that the simulation represents, i.e. the real-world equiva- lent of 'tick 1' (POSIXIt) |

```
read.DeponsDyn
```

Value

DeponsBlockdyn object

See Also

See DeponsBlockdyn-class for details on what is stored in the output object and read.DeponsParam for reading the parameters used in the simulation.

Examples

```
## Not run:
# File loaded from default location
the.file <- "/Applications/DEPONS 2.1/DEPONS/PorpoisePerBlock.2020.Sep.02.20_24_17.csv"
file.exists(the.file)
porpoise.blockdyn <- read.DeponsBlockdyn(fname=the.file,
    title="Test simulation with two blocks", landscape="North Sea")
porpoise.blockdyn
# Get the latest simulation
the.file <- get.latest.sim(type="blockdyn", dir="/Applications/DEPONS 2.1/DEPONS")
owd <- getwd()
setwd("/Applications/DEPONS 2.1/DEPONS")
porpoise.blockdyn <- read.DeponsBlockdyn(fname=the.file)
setwd(owd)
```

End(Not run)

read.DeponsDyn Reading DEPONS simulation output

Description

Function for reading simulation output produced by DEPONS.

Usage

```
read.DeponsDyn(
  fname,
  title = "NA",
  landscape = "NA",
  simtime = "NA",
  startday = "NA",
  timestep = 30,
  tz = "GMT"
)
```

Arguments

| fname | Name of the file (character) that contains number of animals for each time step during the simulation, along with their energy and the amount of food in the landscape. The name includes the path to the directory if this is not the current working directory. |
|-----------|--|
| title | Optional character string giving name of simulation |
| landscape | The landscape used in the simulation |
| simtime | Optional character string with the date and time when the simulation finished (format yyyy-mm-dd). If not provided this is obtained from name of input file |
| startday | The start of the period that the simulation represents, i.e. the real-world equiva- lent of 'tick 1' (character string of the form 'yyyy-mm-dd', or POSIXlt) |
| timestep | Time step used in the model, in minutes. Defaults to 30 in DEPONS. |
| tz | Time zone. |

Value

DeponsDyn object containing simulation output

See Also

See DeponsDyn-class for details on what is stored in the output object.

Examples

```
## Not run:
dyn.file <- "/Applications/DEPONS 2.1/DEPONS/Statistics.2020.Sep.02.20_24_17.csv"
file.exists(dyn.file)
porpoisedyn <- read.DeponsDyn(dyn.file, startday=as.POSIXlt("2010-01-01"))
porpoisedyn
```

End(Not run)

read.DeponsParam Read simulation parameters

Description

Read the parameters that were used for running a specific DEPONS simulation

Usage

read.DeponsParam(fname)

Arguments

fname

Name of the XML file (character) that contains the parameter list used for running a DEPONS simulation. The name includes the path to the directory if this is not the current working directory.

Details

The parameter file can be generated from within DEPONS by pressing the 'Save' icon after modifying the user settings on the 'Parameters' tab within the main DEPONS model window. See TRACE document for details regarding the parameters in the model: https://github.com/jacobnabe/ DEPONS. It is strongly recommended that the parameter list is stored with the simulation output.

Value

Data frame containing all parameters used in a specific simulation

Examples

```
## Not run:
# Parameters read from file created by DEPONS run in interactive mode
the.file <- "/Applications/DEPONS 2.1/DEPONS/DEPONS.rs/parameters.xml"
pfile <- read.DeponsParam(the.file)</pre>
```

End(Not run)

read.DeponsRaster Reading DEPONS raster files

Description

Function for reading raster files that have been used in DEPONS simulations. DEPONS rasters define amount of food available for simulated animals, spatial distribution of food patches, bathymetry, and distance to coast (dtc). The 'blocks' raster enables the user to count animals in specific parts of the landscape during simulations. See Nabe-Nielsen et al. (2018) for details regarding these files. In DEPONS 2.0 the salinity raster file was introduced; see TRACE document for details: https://github.com/jacobnabe/DEPONS

Usage

```
read.DeponsRaster(fname, type = "NA", landscape = "NA", crs = "NA")
```

| fname | Filename (character), including the path to the DEPONS raster file. |
|-----------|---|
| type | The kind of data stored in the raster; c('food', 'patches', 'bathymetry', 'dtc', 'salinity', 'blocks'). |
| landscape | Identifier for the landscape used in the DEPONS simulations; typically set to 'North Sea'. |
| crs | CRS-object providing the map projection (see CRS). |

Value

Returns a DeponsRaster object. The object inherits slots from the "RasterLayer" class, including "title", which is used for storing the file name.

See Also

DeponsRaster-class

read.DeponsShips Read DEPONS ship files

Description

Function for reading the json-files that are used for controlling how ship agents behave in DEPONS. Ships move along pre-defined routes in 30-min time steps. The routes are defined by the fix-points provided in the json file, and the geographic projection is assumed to match that of the landscape.

Usage

```
read.DeponsShips(fname, title = "NA", landscape = "NA", crs = as.character(NA))
```

Arguments

| fname | Name of the file (character) where ship routes and ships are defined. |
|-----------|---|
| title | Optional character string with the name of the simulation |
| landscape | Optional character string with the landscape used in the simulation |
| crs | Character, coordinate reference system (map projection) |

Value

Returns an object with the elements title landscape, crs, routes and ships.

Description

Function for reading movement tracks produced by DEPONS. These describe movements of simulated animals within the simulation landscape, where the positions after each 30-min time step are provided using the coordinate reference system that were used for generating these landscapes. See van Beest et al. (2018) and Nabe-Nielsen et al. (2013) for details regarding how these files were generated as a balance between correlated random walk behaviour and spatial memory behaviour, which allows animals to return to previously visited food patches.

Usage

```
read.DeponsTrack(
  fname,
  title = "NA",
  landscape = "NA",
  simtime = "NA",
  crs = as.character(NA),
  tz = "UTC"
)
```

Arguments

| fname | Name of the file (character) that contains movement data generated by DE- PONS. The name includes the path to the directory if this is not the current working directory. |
|-----------|---|
| title | Optional character string giving name of simulation |
| landscape | Optional character string with the landscape used in the simulation |
| simtime | Character sting with date of simulation (format yyyy-mm-dd). If not provided this is obtained from name of input file |
| crs | Character, coordinate reference system (map projection) |
| tz | Time zone used in simulations. Defaults to UTC/GMT. #' |

Value

Returns a DeponsTrack object with the elements title, simtime, crs, and tracks. The date is extracted from input data if not provided explicitly and stored as a POSIX1t object. The element tracks is a list of objects of class SpatialPointsDataFrame, each of which corresponds to one simulated animal (several animals can be tracked in one simulation).

routes

Examples

```
data(porpoisetrack) # Load data for use in example
# Use standard DEPONS coordinate reference system / map projection:
the.crs <- "+proj=laea +lat_0=52 +lon_0=10 +x_0=4321000 +y_0=3210000
+datum=WGS84 +units=m +no_defs"
## Not run:
one.fname <- "~/Applications/DEPONS/
RandomPorpoise.2020.Jul.31.09_43_10.csv"
porpoisetrack <- read.DeponsTrack(one.fname, title="Track simulated using DEPONS 2.0",
    crs=the.crs)
## End(Not run)
# Plot the first of the simulated tracks
plot(porpoisetrack)</pre>
```

routes

Get or define routes in DeponsShips objects

Description

Get or define routes in DeponsShips objects

Usage

```
## S4 method for signature 'DeponsShips'
routes(x)
```

S4 replacement method for signature 'DeponsShips'
routes(x) <- value</pre>

Arguments

| х | Object of class DeponsShips |
|-------|---|
| value | list with one named element per shipping route. Each element is a data frame with the variables x, y, speed, and 'pause' which define the coordinates of the fix-points on the shipping routes and the speeds that ships have after passing the fix point and until reaching the next fix point. The variable 'pause' instructs ships about how many minutes to wait before continuing to move. |

Note

The unit of 'speed' is knots.

30

shipdata

See Also

ships

shipdata

Hypothetical ships on routes through Kattegat

Description

The ship routes and ships used in the study by Nabe-Nielsen et al. (2014). The fix points that define the routes use the UTM zone 32 projection, (EPSG:32632; see https://epsg.io/32632).

The definitions of the ships has been modified since earlier versions of DEPONS (i.e. 2.1 and erlier) in that it now includes ship length, type, and speed (in knots). These are used for calculating the sound source level (following McGilliwray)

Automatic identification system (AIS) data for three ships in Kattegat and the Western Baltic from 20 Dec 2015. The data set includes the variables id (the Maritime Mobile Service Identity number), time, speed (in knots), type, length (in meters), x and y (which provide the coordinates of the ship at a given time. The coordinates use the UTM zone 32 projection (CRS = "+proj=utm +zone=32 +units=m +no_defs +datum=WGS84"). Data were downloaded from the Danish Maritime Authority web page (https://dma.dk).

DeponsShips-class

ships

Description

Get or define ships in DeponsShips objects

Usage

```
## S4 method for signature 'DeponsShips'
ships(x)
```

```
ships(x) <- value</pre>
```

Arguments

| х | Object of class DeponsShips |
|-------|--|
| value | data frame with the 'name', 'type', 'length', and 'route' of ships to be simulated as well as 'tickStart' and 'tickEnd' defining when the ships are to be included in simulations. 'route' is one of the shipping routes defined in the DeponsShips object. |

startday

Get or set start date for simulation

Description

Get or set start date for simulation

Get or set start date for simulation

Summary-methods

Usage

```
## S4 method for signature 'DeponsBlockdyn'
startday(x)
## S4 method for signature 'DeponsDyn'
startday(x)
## S4 replacement method for signature 'DeponsBlockdyn'
startday(x) <- value
## S4 replacement method for signature 'DeponsDyn'
startday(x) <- value</pre>
```

Arguments

| х | Object of class DeponsDyn |
|-------|---|
| value | POSIXIt or character string of the form 'yyyy-mm-dd |

Details

The start date indicates the start of the period that the simulation is supposed to represent.

The start date indicates the start of the period that the simulation is supposed to represent.

Note

The assignment of a new start time is currently quite time consuming.

Summary-methods Summary

Description

Summarizes different kinds of objects created based on output from the DEPONS model

Usage

```
## S4 method for signature 'DeponsBlockdyn'
summary(object)
## S4 method for signature 'DeponsDyn'
summary(object)
## S4 method for signature 'DeponsRaster'
summary(object)
## S4 method for signature 'DeponsShips'
```

tick.to.time

```
summary(object)
```

S4 method for signature 'DeponsTrack'
summary(object)

Arguments

object Depons* object

Details

The summary method is available for DeponsTrack-class, DeponsDyn-class, DeponsRaster-class, and DeponsBlockdyn-class-objects.

Value

list summarizing the DeponsBlockdyn object

table summarizing the DeponsBlockdyn object

list summarizing the DeponsRaster object

list summarizing the DeponsTrack object

tick.to.time Convert tick number to date

Description

Converts the number of ticks since the start of the simulation to a specific date while taking into account that DEPONS assumes that there are 360 days in a simulation year.

Usage

tick.to.time(tick, timestep = 30, origin = "2010-01-01", ...)

Arguments

| tick | Numeric, or numeric vector; tick number |
|----------|--|
| timestep | Numeric; length of each simulation time step, in minutes. Defaults to 30 minutes. |
| origin | Character. The first day in the period that the simulation represents, format: 'yyyy-mm-dd'. |
| | Optional parameters, including time zone (tz) |

Value

object of class as.POSIXlt

title<-

Note

The function assumes that there are 30 days in each month, except in January, February and March with 31, 28 and 31 days, respectively.

title<-

Get or set the title of Depons* objects

Description

Get or set the title of Depons* objects

Usage

```
## S4 replacement method for signature 'DeponsTrack'
title(x) <- value
## S4 replacement method for signature 'DeponsDyn'
title(x) <- value
## S4 replacement method for signature 'DeponsShips'
title(x) <- value
## S4 method for signature 'DeponsTrack'
title(x, value)
## S4 method for signature 'DeponsDyn'
title(x, value)
## S4 method for signature 'DeponsShips'
title(x, value)</pre>
```

Arguments

| Х | Object of class DeponsTrack, DeponsDyn, DeponsBlockdyn or DeponsShips |
|-------|---|
| value | Character string |

write, DeponsShips-method

Write DEPONS ship files

Description

Function for writing a json-file for controlling how ship agents behave in DEPONS. Ships move along pre-defined routes in 30-min time steps. The routes are defined by the fix-points provided in the json file, and the geographic projection is assumed to match that of the landscape. The projection is not stored as part of the json file.

Usage

```
## S4 method for signature 'DeponsShips'
write(x, file)
```

Arguments

| х | Name of the DeponsShips object to be exported |
|------|---|
| file | Name of the output file (character) |

Value

No return value, called for side effects

Note

The exported json file is intended for use in DEPONS 2.3 or later (released July 2022) where the sound pressure level (SPL) is calculated within DEPONS based on ship type, ship length and speed.
