binomCI 3

binomCI	Confidence Intervals for Binomial Proportions

# **Description**

This function can be used to compute confidence intervals for binomial proportions.

# Usage

```
binomCI(x, n, conf.level = 0.95, method = "wilson", rand = 123,
    R = 9999, bootci.type = "all",
    alternative = c("two.sided", "less", "greater"), ...)
```

## **Arguments**

number of successes Χ number of trials conf.level confidence level method character string specifing which method to use; see details. seed for random number generator; see details. rand number of bootstrap replicates. bootci.type type of bootstrap interval; see boot.ci. alternative a character string specifying one- or two-sided confidence intervals. Must be one of "two.sided" (default), "greater" or "less" (one-sided intervals). You can specify just the initial letter.

#### **Details**

The Wald interval is obtained by inverting the acceptance region of the Wald large-sample normal test. There is also a Wald interval with continuity correction ("wald-cc").

further arguments passed to function boot, e.g. for parallel computing.

The Wilson interval, which is the default, was introduced by Wilson (1927) and is the inversion of the CLT approximation to the family of equal tail tests of p = p0. The Wilson interval is recommended by Agresti and Coull (1998) as well as by Brown et al (2001).

The Agresti-Coull interval was proposed by Agresti and Coull (1998) and is a slight modification of the Wilson interval. The Agresti-Coull intervals are never shorter than the Wilson intervals; cf. Brown et al (2001).

The Jeffreys interval is an implementation of the equal-tailed Jeffreys prior interval as given in Brown et al (2001).

The modified Wilson interval is a modification of the Wilson interval for x close to 0 or n as proposed by Brown et al (2001).

The modified Jeffreys interval is a modification of the Jeffreys interval for  $x == 0 \mid x == 1$  and  $x == n-1 \mid x == n$  as proposed by Brown et al (2001).

4 binomCI

The Clopper-Pearson interval is based on quantiles of corresponding beta distributions. This is sometimes also called exact interval.

The arcsine interval is based on the variance stabilizing distribution for the binomial distribution.

The logit interval is obtained by inverting the Wald type interval for the log odds.

The Witting interval (cf. Beispiel 2.106 in Witting (1985)) uses randomization to obtain uniformly optimal lower and upper confidence bounds (cf. Satz 2.105 in Witting (1985)) for binomial proportions.

The bootstrap interval is calculated by using function boot.ci.

For more details we refer to Brown et al (2001) as well as Witting (1985).

#### Value

A list with class "confint" containing the following components:

```
estimate the estimated probability of success.

conf.int a confidence interval for the probability of success.
```

## Note

A first version of this function appeared in R package SLmisc.

binomDiffCI

Confidence Intervals for Difference of Two Binomial Proportions

## **Description**

This function can be used to compute confidence intervals for the difference of two binomial proportions. It includes methods for the independent and the paired case.

## Usage

#### **Arguments**

a	independent: number of successes of group 1; paired: number of cases with success in group 1 and 2.
b	independent: number of successes of group 2; paired: number of cases with success in group 1 and failure in group 2.
C	independent: number of failures of group 1: paired: number of cases with failure

c independent: number of failures of group 1; paired: number of cases with failure in group 1 and success in group 2.

d independent: number of failures of group 2; paired: number of cases with failure in group 1 and 2.

6 binomDiffCI

conf.level confidence level

paired a logical value indicating whether the two groups are paired.

method character string specifing which method to use; see details.

R number of bootstrap replicates.

bootci.type type of bootstrap interval; see boot.ci.

alternative a character string specifying one- or two-sided confidence intervals. Must be

one of "two.sided" (default), "greater" or "less" (one-sided intervals). You can

specify just the initial letter.

... further arguments passed to function boot, e.g. for parallel computing.

#### **Details**

The Wald intervals (independent and paired) are obtained by applying the normal approximation. There are also Wald intervals with continuity correction.

The Wilson intervals are recommended by Newcombe and Altman (2000); see Chapter 6 of Altman et al. (2000). In the paired case, the continuity corrected version of the interval is recommended. The intervals are proposed in Newcombe (1998a) and Newcombe (1998b).

The bootstrap interval is calculated by using function boot.ci.

#### Value

A list with class "confint" containing the following components:

estimate the estimated probability of success.

conf. int a confidence interval for the probability of success.

8 boot.t.test

boot.t.test

Bootstrap t-Test

#### **Description**

Performs one and two sample bootstrap t-tests on vectors of data.

#### Usage

#### **Arguments**

x a (non-empty) numeric vector of data values.

y an optional (non-empty) numeric vector of data values.

alternative a character string specifying the alternative hypothesis, must be one of "two.sided"

(default), "greater" or "less". You can specify just the initial letter.

mu a number indicating the true value of the mean (or difference in means if you

are performing a two sample test).

paired a logical indicating whether you want a paired t-test.

var.equal a logical variable indicating whether to treat the two variances as being equal.

If TRUE then the pooled variance is used to estimate the variance otherwise the

Welch (or Satterthwaite) approximation to the degrees of freedom is used.

boot.t.test 9

conf.level confidence level of the interval.

R number of bootstrap replicates.

symmetric a logical variable indicating whether to assume symmetry in the two-sided test.

If TRUE then the symmetric bootstrap p value otherwise the equal-tail boostrap p

value is computed.

formula a formula of the form 1hs ~ rhs where 1hs is a numeric variable giving the data

values and rhs a factor with two levels giving the corresponding groups.

data an optional matrix or data frame (or similar: see model.frame) containing

the variables in the formula formula. By default the variables are taken from

environment(formula).

subset an optional vector specifying a subset of observations to be used.

na.action a function which indicates what should happen when the data contain NAs. De-

faults to getOption("na.action").

... further arguments to be passed to or from methods.

#### **Details**

The implemented test corresponds to the proposal of Chapter 16 of Efron and Tibshirani (1993).

The function returns bootstrapped p values and confidence intervals as well as the results of the t-test without bootstrap.

The formula interface is only applicable for the 2-sample tests.

alternative = "greater" is the alternative that x has a larger mean than y.

If paired is TRUE then both x and y must be specified and they must be the same length. Missing values are silently removed (in pairs if paired is TRUE). If var.equal is TRUE then the pooled estimate of the variance is used. By default, if var.equal is FALSE then the variance is estimated separately for both groups and the Welch modification to the degrees of freedom is used.

If the input data are effectively constant (compared to the larger of the two means) an error is generated.

#### Value

A list with class "boot.htest" (derived from class htest) containing the following components:

statistic the value of the t-statistic.

parameter the degrees of freedom for the t-statistic.

p.value the p-value for the test.

boot.p.value the bootstrapped p-value for the test.

conf.int a confidence interval for the mean appropriate to the specified alternative hy-

pothesis.

boot.conf.int a bootstrap percentile confidence interval for the mean appropriate to the speci-

fied alternative hypothesis.

estimate the estimated mean or difference in means depending on whether it was a one-

sample test or a two-sample test.

10 boot.t.test

boot.estimate	bootstrapped estimate.
null.value	the specified hypothesized value of the mean or mean difference depending on whether it was a one-sample test or a two-sample test.
stderr	the standard error of the mean (difference), used as denominator in the t-statistic formula.
boot.stderr	bootstrapped standard error.
alternative	a character string describing the alternative hypothesis.
method	a character string indicating what type of t-test was performed.

#### Note

Code and documentation are for large parts identical to function t.test.

#### References

data.name

B. Efron, R.J. Tibshirani. An Introduction to the Bootstrap. Chapman and Hall/CRC 1993.

a character string giving the name(s) of the data.

cvCI 11

cvCI

Confidence Intervals for Coefficient of Variation

# Description

This function can be used to compute confidence intervals for the (classical) coefficient of variation.

## Usage

```
cvCI(x, conf.level = 0.95, method = "miller", R = 9999,
    bootci.type = c("norm", "basic", "perc", "bca"), na.rm = FALSE,
    alternative = c("two.sided", "less", "greater"), ...)
```

## **Arguments**

x numeric vector with positive numbers.

conf.level confidence level

method character string specifing which method to use; see details.

R number of bootstrap replicates; see details.

bootci.type type of bootstrap interval; see boot.ci. Type "student" does not work.

na.rm logical. Should missing values be removed?

alternative a character string specifying one- or two-sided confidence intervals. Must be

one of "two.sided" (default), "greater" or "less" (one-sided intervals). You can

specify just the initial letter.

... further arguments passed to function boot, e.g. for parallel computing.

#### **Details**

For details about the confidence intervals we refer to Gulhar et al (2012) and Arachchige et al (2019)

In case of bootstrap intervals type "student" does not work, since no standard error of CV is provided.

# Value

A list with class "confint" containing the following components:

estimate the estimated coefficient of variation.

conf. int a confidence interval for the coefficient of variation.

hsu.t.test

Hsu Two-Sample t-Test

## **Description**

Performs Hsu two sample t-tests on vectors of data.

## Usage

```
hsu.t.test(x, ...)
## Default S3 method:
```

13 hsu.t.test

```
hsu.t.test(x, y,
       alternative = c("two.sided", "less", "greater"),
      mu = 0, conf.level = 0.95, ...)
## S3 method for class 'formula'
hsu.t.test(formula, data, subset, na.action, ...)
```

#### **Arguments**

Χ a (non-empty) numeric vector of data values. У alternative a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter. a number indicating the true value of the mean (or difference in means if you mu are performing a two sample test). conf.level confidence level of the interval. formula a formula of the form 1hs ~ rhs where 1hs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups. data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from

environment(formula).

an optional vector specifying a subset of observations to be used. subset

a (non-empty) numeric vector of data values.

na.action a function which indicates what should happen when the data contain NAs. De-

faults to getOption("na.action").

further arguments to be passed to or from methods. . . .

### **Details**

The function and its documentation was adapted from t.test.

alternative = "greater" is the alternative that x has a larger mean than y.

If the input data are effectively constant (compared to the larger of the two means) an error is generated.

One should at least have six observations per group to apply the test; see Section 6.8.3 and 7.4.4.2 of Hedderich and Sachs (2018).

#### Value

A list with class "htest" containing the following components:

statistic the value of the t-statistic.

the degrees of freedom for the t-statistic. parameter

p.value the p-value for the test.

conf.int a confidence interval for the mean appropriate to the specified alternative hy-

pothesis.

the estimated means and standard deviations. estimate

14 imputeSD

null.value the specified hypothesized value of the mean or mean difference depending on

whether it was a one-sample test or a two-sample test.

stderr the standard error of the difference in means, used as denominator in the t-

statistic formula.

alternative a character string describing the alternative hypothesis.

method a character string indicating what type of t-test was performed.

data. name a character string giving the name(s) of the data.

imputeSD

Impute Standard Deviations for Changes from Baseline

# Description

The function imputes standard deviations for changes from baseline adopting the approach describe in the Cochrane handbook, Section 16.1.3.2.

# Usage

```
imputeSD(SD1, SD2, SDchange, corr)
```

imputeSD 15

# **Arguments**

SD1	numeric vector, baseline SD.
SD2	numeric vector, follow-up SD.

SDchange numeric vector, SD for changes from baseline.

corr optional numeric vector of correlations; see details below.

#### **Details**

The function imputes standard deviations for changes from baseline adopting the approach describe in the Cochrane handbook (2019), Section 6.5.2.8.

- 1) Missing SD1 are replaced by correspondig values of SD2 and vice versa.
- 2) Correlations for complete data (rows) are computed. Alternatively, correlations can be provided via argument corr. This option may particularly be useful, if no complete data is available.
- 3) Minimum, mean and maximum correlation (over rows) are computed.
- 4) Missing values of SDchange are computed by the formula provided in the handbook. The minimum, mean and maximum correlation are used leading to maximal, mean and minimal SD values that may be used for imputation as well as a sensitivity analysis.

#### Value

data.frame with possibly imputed SD1 and SD2 values as well as the given SDchange values are returen. Moreover, the computed correlations as well as possible values for the imputation of SDchange are returned.

16 mi.t.test

mi.t.test

Multiple Imputation Student's t-Test

## **Description**

Performs one and two sample t-tests on multiple imputed datasets.

# Usage

# Arguments

miData	list of multiple imputed datasets.
x	name of a variable that shall be tested.
У	an optional name of a variable that shall be tested (paired test) or a variable that shall be used to split into groups (unpaired test).
alternative	a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.
mu	a number indicating the true value of the mean (or difference in means if you are performing a two sample test).
paired	a logical indicating whether you want a paired t-test.
var.equal	a logical variable indicating whether to treat the two variances as being equal. If TRUE then the pooled variance is used to estimate the variance otherwise the Welch (or Satterthwaite) approximation to the degrees of freedom is used.
conf.level	confidence level of the interval.
subset	an optional vector specifying a subset of observations to be used.
	further arguments to be passed to or from methods.

## **Details**

alternative = "greater" is the alternative that x has a larger mean than y.

If paired is TRUE then both x and y must be specified and they must be the same length. Missing values are not allowed as they should have been imputed. If var.equal is TRUE then the pooled estimate of the variance is used. By default, if var.equal is FALSE then the variance is estimated separately for both groups and the Welch modification to the degrees of freedom is used.

We use the approach of Rubin (1987) in combination with the adjustment of Barnard and Rubin (1999).

mi.t.test 17

#### Value

A list with class "htest" containing the following components:

the value of the t-statistic. statistic parameter the degrees of freedom for the t-statistic. p.value the p-value for the test. conf.int a confidence interval for the mean appropriate to the specified alternative hypothesis. the estimated mean (one-sample test), difference in means (paired test), or estiestimate mated means (two-sample test) as well as the respective standard deviations. null.value the specified hypothesized value of the mean or mean difference depending on whether it was a one-sample test or a two-sample test. alternative a character string describing the alternative hypothesis. method a character string indicating what type of t-test was performed.

a character string giving the name(s) of the data.

normCI

Confidence Intervals for Mean and Standard Deviation

## **Description**

This function can be used to compute confidence intervals for mean and standard deviation of a normal distribution.

## Usage

## **Arguments**

x vector of observations.
 mean if known otherwise NULL.
 sd standard deviation if known otherwise NULL.

normCI 19

conf.level confidence level.

boot a logical value indicating whether bootstrapped confidence intervals shall be

computed.

R number of bootstrap replicates.

bootci.type type of bootstrap interval; see boot.ci.

na.rm a logical value indicating whether NA values should be stripped before the com-

putation proceeds.

alternative a character string specifying one- or two-sided confidence intervals. Must be

one of "two.sided" (default), "greater" or "less" (one-sided intervals). You can

specify just the initial letter.

. . . further arguments passed to function boot, e.g. for parallel computing.

## **Details**

The standard confidence intervals for mean and standard deviation are computed that can be found in many textbooks, e.g. Chapter 4 in Altman et al. (2000).

In addition, bootstrap confidence intervals for mean and/or SD can be computed, where function boot.ci is applied.

#### Value

A list with class "confint" containing the following components:

estimate the estimated mean and sd.

conf. int confidence interval(s) for mean and/or sd.

Infos additional information.

#### Author(s)

normDiffCI

Confidence Intervals for Difference of Means

## **Description**

This function can be used to compute confidence intervals for difference of means assuming normal distributions.

# Usage

## Arguments

```
x numeric vector of data values of group 1.
y numeric vector of data values of group 2.
conf.level confidence level.
```

normDiffCI 21

paired a logical value indicating whether the two groups are paired.

method a character string specifing which method to use in the unpaired case; see details.

boot a logical value indicating whether bootstrapped confidence intervals shall be

computed.

R number of bootstrap replicates.

bootci.type type of bootstrap interval; see boot.ci.

na.rm a logical value indicating whether NA values should be stripped before the com-

putation proceeds.

alternative a character string specifying one- or two-sided confidence intervals. Must be

one of "two.sided" (default), "greater" or "less" (one-sided intervals). You can

specify just the initial letter.

... further arguments passed to function boot, e.g. for parallel computing.

#### **Details**

The standard confidence intervals for the difference of means are computed that can be found in many textbooks, e.g. Chapter 4 in Altman et al. (2000).

The method "classical" assumes equal variances whereas methods "welch" and "hsu" allow for unequal variances. The latter two methods use different formulas for computing the degrees of freedom of the respective t-distribution providing the quantiles in the confidence interval. Instead of the Welch-Satterhwaite equation the method of Hsu uses the minimum of the group sample sizes minus 1; see Section 6.8.3 of Hedderich and Sachs (2018).

# Value

A list with class "confint" containing the following components:

estimate point estimate (mean of differences or difference in means).

conf.int confidence interval.

Infos additional information.

p2ses

Compute SES from p value.

# **Description**

The function computes the SES (standardized effect size) from the p value for permutation/randomisation tests as proposed by Botta-Dukat (2018).

# Usage

```
p2ses(p, alternative = c("two.sided", "less", "greater"))
```

# **Arguments**

p numeric vector of p values.

alternative a characte

a character string specifying the alternative hypothesis, must be one of "two.sided"

(default), "greater" or "less". You can specify just the initial letter.

### **Details**

The function uses the probit transformation (qnorm) to compute an alternative SES based on p values from a permutation/randomization test as proposed by Botta-Dukat (2018) for skewed distributions.

#### Value

**SES** 

# Author(s)

Matthias Kohl <Matthias.Kohl@stamats.de>

#### References

24 pairwise.ext.t.test

## **Examples**

```
## symmetric case
x <- rnorm(100)
res <- perm.t.test(x)
p2ses(res$p.value)
abs(res$statistic)

## skewed case
x <- rgamma(100, shape = 5)
res <- perm.t.test(x, mu = 5)
p2ses(res$p.value)
abs(res$statistic)</pre>
```

pairwise.ext.t.test

Compute Pairwise t Tests

# **Description**

The function computes pairwise t tests using functions t.test, boot.t.test or perm.t.test.

## Usage

# **Arguments**

x numeric vector.

g grouping vector or factor

method character giving the name of the function to be applied; that is, "t.test", "hsu.t.test", "boot.t.test" or "perm.t.test".

p.adjust.method method for adjusting p values (see p.adjust). Can be abbreviated.

paired a logical indicating whether you want a paired test.

... additional arguments to fun.

#### **Details**

The function computes pairwise t tests using function t.test, hsu.t.test, boot.t.test or perm.t.test.

The implementation is in certain aspects analogously to pairwise.t.test. However, a more detailed output is generated.

pairwise.fun 25

# Value

Object of class "pw.htest" containing the following components:

data.name a character string giving the names of the data.

method the type of test applied.
null.value the location parameter mu.

alternative a character string describing the alternative hypothesis.

conf.level confidence level of the confidence interval.

results a data.frame containing the results of function t.test, boot.t.test or perm.t.test.

## in contrast to
pairwise.wilcox.test(x, g)</pre>
```

28 perm.t.test

perm.t.test

Permutation t-Test

## **Description**

Performs one and two sample permutation t-tests on vectors of data.

# Usage

### **Arguments**

subset

a (non-empty) numeric vector of data values. Χ an optional (non-empty) numeric vector of data values. У a character string specifying the alternative hypothesis, must be one of "two.sided" alternative (default), "greater" or "less". You can specify just the initial letter. a number indicating the true value of the mean (or difference in means if you mu are performing a two sample test). paired a logical indicating whether you want a paired t-test. var.equal a logical variable indicating whether to treat the two variances as being equal. If TRUE then the pooled variance is used to estimate the variance otherwise the Welch (or Satterthwaite) approximation to the degrees of freedom is used. conf.level confidence level of the interval. R number of (Monte-Carlo) permutations. symmetric a logical variable indicating whether to assume symmetry in the two-sided test. If TRUE then the symmetric permutation p value otherwise the equal-tail permutation p value is computed. formula a formula of the form 1hs ~ rhs where 1hs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups. data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

an optional vector specifying a subset of observations to be used.

perm.t.test 29

na.action a function which indicates what should happen when the data contain NAs. De-

faults to getOption("na.action").

... further arguments to be passed to or from methods.

#### **Details**

The implemented test corresponds to the proposal of Chapter 15 of Efron and Tibshirani (1993) for equal variances as well as Janssen (1997) respectively Chung and Romano (2013) for unequal variances.

The function returns permutation p values and confidence intervals as well as the results of the t-test without permutations.

The formula interface is only applicable for the 2-sample tests.

alternative = "greater" is the alternative that x has a larger mean than y.

If paired is TRUE then both x and y must be specified and they must be the same length. Missing values are silently removed (in pairs if paired is TRUE). If var.equal is TRUE then the pooled estimate of the variance is used. By default, if var.equal is FALSE then the variance is estimated separately for both groups and the Welch modification to the degrees of freedom is used.

If the input data are effectively constant (compared to the larger of the two means) an error is generated.

#### Value

A list with class "perm. htest" (derived from class htest) containing the following components:

statistic the value of the t-statistic.

parameter the degrees of freedom for the t-statistic.

p. value the p-value for the test.

perm.p.value the (Monte-Carlo) permutation p-value for the test.

conf.int a confidence interval for the mean appropriate to the specified alternative hy-

pothesis.

perm. conf. int a (Monte-Carlo) permutation percentile confidence interval for the mean appro-

priate to the specified alternative hypothesis.

estimate the estimated mean or difference in means depending on whether it was a one-

sample test or a two-sample test.

perm. estimate (Monte-Carlo) permutation estimate.

null.value the specified hypothesized value of the mean or mean difference depending on

whether it was a one-sample test or a two-sample test.

stderr the standard error of the mean (difference), used as denominator in the t-statistic

formula.

perm.stderr (Monte-Carlo) permutation standard error.

alternative a character string describing the alternative hypothesis.

method a character string indicating what type of t-test was performed.

data. name a character string giving the name(s) of the data.

30 quantileCI

#### Note

Code and documentation are for large parts identical to function t.test.

# Examples

quantileCI

Confidence Intervals for Quantiles

# Description

These functions can be used to compute confidence intervals for quantiles (including median).

# Usage

quantileCI 31

## **Arguments**

x numeric data vector

prob quantile

conf.level confidence level

method character string specifing which method to use; see details.

R number of bootstrap replicates.

bootci.type type of bootstrap interval; see boot.ci.

na.rm logical, remove NA values.

constant scale factor (see mad).

alternative a character string specifying one- or two-sided confidence intervals. Must be

one of "two.sided" (default), "greater" or "less" (one-sided intervals). You can

specify just the initial letter.

... further arguments passed to function boot, e.g. for parallel computing.

# **Details**

The exact confidence interval (method = "exact") is computed using binomial probabilities; see Section 6.8.1 in Sachs and Hedderich (2009). If the result is not unique, i.e. there is more than one interval with coverage proability closest to conf.level, then a matrix of confidence intervals is returned.

The asymptotic confidence interval (method = "asymptotic") is based on the normal approximation of the binomial distribution; see Section 6.8.1 in Sachs and Hedderich (2009).

In case of discrete data, there are alternative bootstrap approaches that might give better results; see Jentsch and Leucht (2016).

#### Value

A list with components

estimate the sample quantile.

CI a confidence interval for the sample quantile.

#### Author(s)

Matthias Kohl <Matthias.Kohl@stamats.de>

rm.oneway.test 33

ncpus = 2)

rm.oneway.test

Test for Equal Means in a Repeated Measures One-Way Layout

#### **Description**

Test whether two or more samples have the same locations in a repeated measures setting.

## Usage

```
rm.oneway.test(x, g, id, method = "aov")
```

# **Arguments**

x numeric, response (outcome, dependent) variable.

g factor, grouping (independent) variable.
id factor, subject id (blocking variable).

method name of method, possible methods are "aov", "lme", "friedman", "quade"

#### **Details**

The function wraps the functions aov, lme, friedman.test and quade.test into one function for a repeated measures one-way layout.

# Value

A list with class "htest" containing the following components:

statistic the value of the test statistic.

parameter the degrees of freedom of the exact or approximate F distribution of the test

statistic.

p.value the p-value of the test.

method a character string indicating the test performed.
data.name a character string giving the names of the data.

volcano

Volcano Plots

## **Description**

Produce volcano plot(s) of the given effect size and p values.

## Usage

## Arguments

```
x in case of default method: measure of effect size.

pval numeric, (adjusted) p values.

effect0 single numeric, value for no effect.

sig.level single numeric, significance level.

effect.low NULL or single numeric, boundary for low effect sizes.

effect.high NULL or single numeric, boundary for low effect sizes.
```

volcano 35

color.low	color used if effect size smaller than effect.low and (adjusted) p value smaller than sig.level.
color.high	color used if effect size larger than effect.high and (adjusted) p value smaller than ${\tt sig.level}.$
xlab	label of x-axis.
ylab	label of y-axis.
title	title of plot.
alpha	bleding factor (default: no blending.
shape	point shape used.
na.rm	logical, remove NA values before plotting.
	further arguments that may be passed through).

#### **Details**

The plot generates a ggplot2 object that is shown.

Missing values are handled by the ggplot2 functions.

## Value

Object of class gg and ggplot.
