Package 'MSclassifR'

October 12, 2022

Type Package

Title Automated Classification of Mass Spectra

Version 0.3.1

Maintainer Alexandre Godmer <alexandre.godmer@aphp.fr>

Description

Functions to classify mass spectra in known categories, and to determine discriminant mass-over-charge values. It includes easy-to-use functions for pre-processing mass spectra, functions to determine discriminant mass-over-charge values (m/z) from a library of mass spectra corresponding to different categories, and functions to predict the category (species, phenotypes, etc.) associated to a mass spectrum from a list of selected mass-over-charge values. Three vignettes illustrating how to use the functions of this package from real data sets are also available online to help users: <a href="https://agodmer.github.io/MSclassifR_examples/Vignettes/V

CitrobacterRKImetadata

Metadata of mass spectra corresponding to the bacterial species Citrobacter sp. from The Robert Koch-Institute (RKI) database of microbial MALDI-TOF mass spectra

Description

Metadada of the CitrobacterRKIspectra list of mass spectra.

Usage

```
data("CitrobacterRKImetadata", package = "MSclassifR")
```

Format

A data frame with 14 rows (each corresponding to a mass spectrum), and five columns that contain (in order): the strain name, the species name, the spot, a sample number and the name of the strain associated with the spot.

Details

The Robert Koch-Institute (RKI) database of microbial MALDI-TOF mass spectra contains raw mass spectra. Only mass spectra of the *Citrobacter* bacterial species were collected. Metadata were manually reported from raw data.

Source

The raw data were downloaded from this link: https://zenodo.org/record/163517#.YIkWiNZuJCp. The dataset focuses only on mass spectra from *Citrobacter*.

CitrobacterRKIspectra Mass spectra corresponding to the bacterial species Citrobacter sp. from The Robert Koch-Institute (RKI) database of microbial MALDI-TOF mass spectra

Description

Mass spectra of the CitrobacterRKIspectra dataset.

Usage

```
data("CitrobacterRKIspectra", package = "MSclassifR")

#####
#Plotting the first mass spectrum
#library("MSclassifR")
#PlotSpectra(SpectralData=CitrobacterRKIspectra[[1]],absx = "ALL", Peaks = NULL,
# Peaks2 = NULL, col_spec = 1, col_peak = 2, shape_peak = 3,
# col_peak2 = 2, shape_peak2 = 2)
```

Format

A list that contains 14 objects of class S4 corresponding each to a each mass spectrum.

Details

The Robert Koch-Institute (RKI) database of microbial MALDI-TOF mass spectra contains raw mass spectra. Only mass spectra of the *Citrobacter* bacterial species were collected.

Source

The raw data were downloaded from this link: https://zenodo.org/record/163517#.YIkWiNZuJCp. The dataset focuses only on mass spectra from *Citrobacter*.

LogReg	Estimation of a multinomial logistic regression to predict the category to which a mass spectrum belongs
	to which a mass spectrum octorigs

Description

This function estimates a multinomial logistic regression using cross-validation to predict the category (species, phenotypes...) to which a mass spectrum belongs from a set of shortlisted mass-over-charge values corresponding to discriminant peaks. Two main kinds of models can be estimated: linear or nonlinear (with neural networks, random forests, support vector machines with linear kernel, or eXtreme Gradient Boosting). Hyperparameters are randomly searched, except for the eXtreme Gradient Boosting where a grid search is performed.

Usage

Arguments

Χ	matrix corresponding to a library of mass spectra. Each row of X is the inten-
	sities of a mass spectrum measured on the moz values. The columns should be
	represented by mass-over-charge values.

moz vector with shortlisted mass-over-charge values.

Y factor with a length equal to the number of rows in X and containing the cate-

gories of each mass spectrum in X.

number integer corresponding to the number of folds or number of resampling itera-

tions. See arguments of the trainControl function of the caret R package.

Metric a charater indicating metric to select the optimal model. The possibles metrics

are the "Kappa" coefficient, "Accruracy", the "F1" score, "AdjRankIndex" for the Adjusted Rand Index or "MatthewsCorrelation" for the Matthews Corre-

lation Coefficient.

repeats integer corresponding to the number of complete sets of folds to compute. See

trainControl function of the caret R package for more details.

kind If kind="nnet", then a nonlinear multinomial logistic regression is estimated

via neural networks. If kind="rf", then it is estimated via random forests. If kind="svm", then it is estimated via support vector machines with linear kernel. If kind="xgb", then it is estimated via eXtreme gradient boosting. Else a linear

multinomial logistic regression is performed (by default).

Sampling

a charater indicating an optional subsampling method to handle imbalanced datasets. The possibles methods to rebalance the data are "up", "down" and "smote".

Details

This function estimates a model from a library of mass spectra for which we already know the category to which they belong (ex.: species, etc). This model can next be used to predict the category of a new coming spectrum for which the category is unknown (see PredictLogReg).

The estimation is performed using the train function of the caret R package. For each kind of model, random parameters are tested to find a model according to the best metric. The formulas for the metric are as follows:

Accuracy = Number Of Correct Predictions / Total Number Of Predictions

Kappacoefficient = ObservedAgreement - ChanceAgreement/1 - ChanceAgreement

F1 = TruePositive / (TruePositive + 1/2(FalsePositive + FalseNegative))

The adjusted Rand index ("AdjRankIndex") is defined as the corrected-for-chance version of the Rand index which allows you to compare two groups, see mclust package and adjustedRandIndex() function for more details. The Matthews correlation coefficient ("MatthewsCorrelation") which measures the association of two variables is calculated using mcc function in the mltools R package.

For Sampling methods available for unbalanced data: "up" corresponds to the up-sampling method which consists of random sampling (with replacement) so that the minority class is the same size as the majority class; "down" corresponds to the down-sampling method randomly which consists of random sampling (without replacement) of the majority class so that their class frequencies match the minority class; "smote" correspond to the Synthetic Minority Over sampling Technique (SMOTE) specific algorithm for data augmentation which consist of creating new data from minority class using the K Nearest Neighbor algorithm.

Value

Returns a list with four items:

train_mod	a list corresponding to the output of the train function of the caret R package containing the multinomial regression model estimated using repeated cross-validation.
conf_mat	a confusion matrix containing percentages classes of predicted categories in function of actual categories, resulting from repeated cross-validation.
stats_global	a data frame containing the mean and standard deviation values of the "Accuracy"" and "Kappa" parameters computed for each cross-validation.
boxplot	a ggplot object (see ggplot2 R package). This is a graphical representation of the Metric parameters of stats_global using boxplots.

```

MSclassifR 9

MSclassifR

Automated classification of mass spectra

Description

This package provides R functions to classify mass spectra in known categories, and to determine discriminant mass-over-charge values. It was developed with the aim of identifying very similar species or phenotypes of bacteria from mass spectra obtained by Matrix Assisted Laser Desorption Ionisation - Time Of Flight Mass Spectrometry (MALDI-TOF MS). However, the different functions of this package can also be used to classify other categories associated to mass spectra; or from mass spectra obtained with other mass spectrometry techniques. It includes easy-to-use functions for pre-processing mass spectra, functions to determine discriminant mass-over-charge values (m/z) from a library of mass spectra corresponding to different categories, and functions to predict the category (species, phenotypes, etc.) associated to a mass spectrum from a list of selected mass-over-charge values.

Value

No return value. Package description.

Author(s)

Alexandre Godmer, Quentin Giai Gianetto

10 PeakDetection

PeakDetection

Detection of peaks in MassSpectrum objects.

Description

This function performs a data analysis pipeline to pre-process mass spectra. It provides average intensities and detects peaks using functions of R packages MALDIquant and MALDIrppa.

Usage

Arguments

x a list of MassSpectrum objects (see MALDIquant R package).

labels a list of factor objects to do groupwise averaging.

averageMassSpectraMethod

a character indicating the method used to average mass spectra according to labels. It is fixed to "median" by default. This function can be replaced by another mathematical function such as "mean". See average Mass Spectra of MALDI quant R package.

PeakDetectionMethod

a character indicating the noise estimation method. It uses "MAD" method for list of MassSpectrum objects. This noise estimation method estimation method can be remplaced "SuperSmoother". See estimateNoise-methods of the MALDIquant R package for details.

SNRdetection

a numeric value indicating the signal-to-noise ratio used to detect peaks (by default = 3). See detectPeaks-methods of the MALDIquant R package for details.

halfWindowSizeDetection

a numeric value half window size to detect peaks (by default = 11). See detectPeaks-methods of the MALDIquant R package for details.

AlignMethod

a character indicating the method used to equalize masses for similar peaks. The "strict" method is used by default corresponding to a unique peak per bin from the same sample. This method can be remplaced by "relaxed" corresponding to multiple peaks per bin from the same sample. See binPeaks of the MALDIquant R package for more details.

PeakDetection 11

Tolerance a numeric value corresponding to the maximal deviation in peak masses to be considered as identical in ppm (by default = 0.002). See determineWarpingFunctions

of the MALDIquant R package for details.

... other arguments from MALDIquant and MALDIrppa packages.

Details

The PeakDetection function provides an analysis pipeline for MassSpectrum objects including peaks detection and binning.

All the methods used for PeakDetection functions are selected from MALDIquant and MALDIrppa packages.

Value

Returns a list of MassPeaks objects (see MALDIquant R package) for each mass spectrum in x.

12 PlotSpectra

PlotSpectra	Plot mass spectra with detected peaks
-------------	---------------------------------------

Description

This function performs a plot of a AbstractMassObject object (see the MALDIquant R package). It can be used to highlight peaks in a mass spectrum.

Usage

```
PlotSpectra(SpectralData, absx="ALL", Peaks=NULL, Peaks2=NULL, col_spec=1, col_peak=2, shape_peak=3, col_peak2=2, shape_peak2=2)
```

Arguments

SpectralData absx	MassSpectrum object of S4 class (see MALDIquant R package). vector indicating lower and upper bounds for the mass-over-charge values to
	plot.
Peaks	$\label{eq:massPeaks} \mbox{ MassPeaks object (see MALDIquant R package). If NULL, peaks are not highlighted.}$
Peaks2	numeric vector of mass-over-charge values to plot on the mass spectrum.
col_spec	color of the mass spectrum.
col_peak	color of the peak points corresponding to Peaks.
shape_peak	shape of the peak points corresponding to Peaks.
col_peak2	color of the peak points corresponding to Peaks2.
shape_peak2	Shape of the peak points corresponding to Peaks2.

Value

A ggplot object (see ggplot2 R package). Mass-over-charge values are in x-axis and intensities in y-axis.

```
library("MSclassifR")

# Load mass spectra
data("CitrobacterRKIspectra", package = "MSclassifR")

# Plot raw mass spectrum
PlotSpectra(SpectralData = CitrobacterRKIspectra[[1]])
# standard pre-processing of mass spectra
spectra <- SignalProcessing(CitrobacterRKIspectra)
# Plot pre-processed mass spectrum</pre>
```

PredictFastClass 13

```
PlotSpectra(SpectralData=spectra[[1]])
# detection of peaks in pre-processed mass spectra
peaks <- PeakDetection(x = spectra, labels = CitrobacterRKImetadata$Strain_name_spot)
# Plot peaks on pre-processed mass spectrum
PlotSpectra(SpectralData=spectra[[1]],Peaks=peaks[[1]],col_spec="blue",col_peak="black")</pre>
```

PredictFastClass

Prediction of the category to which a mass spectrum belongs using linear regressions of mass spectra.

Description

For each mass peak in a list of mass peaks, a linear regression is performed between the mass spectrum and mass spectra corresponding to a category. This is performed for each category and associated to an Akaike Information Criterium. Next, the AIC are used to determine the belonging of a mass spectrum to a category. It also provides a probability that the mass spectrum does not belong to any of the input categories.

Usage

Arguments

peaks

1
an intensity matrix corresponding to mass spectra for which the category is known. Each column is a mass-over-charge value, each row corresponds to a mass spectrum.
a factor with a length equal to the number of mass spectra in mod_peaks and containing the categories of each mass spectrum in mod_peaks.
a vector with the set of shortlisted mass-over-charge values that corresponds to mass-over-charge values in the columns of mod_peaks. By default, all the mass-over-charge values in mod_peaks are used.

a list of MassPeaks objects (see MALDIquant R package).

tolerance a numeric value of accepted tolerance to match peaks to the set of shortlisted mass-over-charge values. It is fixed to 6 Da by default.

toleranceStep a numeric value added to the tolerance parameter to match peaks to the set of shortlisted mass-over-charge values. It is fixed to 2 Da by default.

14 PredictFastClass

normalizeFun a logical value, if TRUE (default) the maximum intensity will be equal to 1, the

other intensities will be expressed in ratio to this maximum.

noMatch a numeric value used to replace intensity values if there is no match detected

between peaks and the set of shortlisted mass-over-charge values moz. It is fixed

to 0 by default.

Value

Returns a dataframe containing AIC criteria by category for each mass spectrum in peaks. The AIC criterion should be minimal for the most probable category. The pred_cat column is the predicted category for each mass spectrum in peaks. The p_not_in_DB is the minimal p-value of several Fisher tests testing if all the linear coefficients associated to mass spectra of a category are null. It can be interpreted as a p-value that the mass spectrum is not present in the input database.

```

PredictLogReg

Prediction of the category to which a mass spectrum belongs from a multinomial logistic regression model

Description

This function predicts the category (species, phenotypes...) to which a mass spectrum belongs from a set of shortlisted mass-over-charge values of interest and a short-listed multinomial logistic regression model (see LogReg).

Usage

Arguments

peaks a list of MassPeaks objects (see MALDIquant R package).

model a model or a list of models estimated from a set of shortlisted mass-over-charge

values (output of the LogReg function).

moz a vector with the set of shortlisted mass-over-charge values used to estimate

the model Model.

tolerance a numeric value of accepted tolerance to match peaks to the set of shortlisted

mass-over-charge values. It is fixed to 6 Da by default.

toleranceStep a numeric value added to the tolerance parameter to match peaks to the set of

shortlisted mass-over-charge values. It is fixed to 2 Da by default.

normalizeFun a logical value, if TRUE (default) the maximum intensity will be equal to 1, the

other intensities will be expressed in ratio to this maximum.

noMatch a numeric value used to replace intensity values if there is no match detected

between peaks and the set of shortlisted mass-over-charge values moz. It is fixed

to 0 by default.

Reference a factor with a length equal to the number of rows in X and containing the

categories of each mass spectrum in X. "NULL" by default.

Details

The PredictLogReg function allows to predict the membership of a mass spectrum to a category from a multinomial logistic regression model. The mass spectrum from the peaks object will be matched to the discriminant mass-over-chage (m/z) values (sel_moz object from the SelectionVar function) with a tolerance between two m/z defined by the tolerance parameter (by default this value is 6 Da). If a repetition of same m/z occurs in the selection, only the m/z that is closest in mass peaks (moz) is used. When no match, intensity values are replaced by the noMatch argument. If no m/z values from peaks object matched with the m/z in the object moz, the tolerance will be increased according to a numeric value defined in the toleranceStep parameter and a warning will be notified. Note that it is possible to not perform the SelectionVar function prior to the PredictLogReg function, and to replace the argument moz by all the m/z values present in a mass spectrum.

Value

Returns a dataframe containing probabilities of membership by category for each mass spectrum in peaks. The method used is provided in the method column. The comb_fisher method is the result

of the Fisher's method when merging probabilities of membership of used prediction models. The max_vote method is the result of the maximum voting from used prediction models.

If the Reference parameter is not null, the function returns:

Confusion.Matrix

a list of confusion matrix (cross-tabulation with associated statitics) corresponding to the output of the confusionMatrix function of the caret R package.

Gobal.stat

a data.frame with three columns corresponding to the value (value column) of a statistic parameter (Statistic.parameter column) from a method used (model column) obtained with the LogReg function. See LogReg function for the Statistic.parameter column.

Details.stat

a data.frame with four columns corresponding to the same as Gobal.stat dataframe with the class concerned for estimated statistic parameter (class column). All statistic parameters are extracted from the output of the confusionMatrix function of the caret R package.

Correct.ClassificationFreq

a data.frame with predicted class (Prediction column) from a method (Model column) and the reference of the categories of each mass spectrum (Reference column). The Freq column indicates the number of times the category was correctly predicted by the method.

Incorrect.ClassificationFreq

a data.frame with predicted class (Prediction column) from a method (Model column) and the reference of the categories of each mass spectrum (Reference column). The Freq column indicates the number of times the category was not correctly predicted by the method.

```

SelectionVar

Variable selection using random forests, logistic regression methods or sparse partial least squares discriminant analysis (sPLS-DA).

Description

This function performs variable selection (i.e. selection of discriminant mass-over-charge values) using either recursive feature elimination (RFE) algorithm with Random Forest, or logistic regression model, or sparse partial least squares discriminant analysis (sPLS-DA).

Usage

SelectionVar 21

Arguments

X a numeric matrix corresponding to a library of mass spectra. Each row of X is

the intensities of a mass spectrum measured on mass-over-charge values.T he

columns should be represented by mass-over-charge values.

Y a factor with a length equal to the number of rows in X and containing the

categories of each mass spectrum in X.

MethodSelection

a charater indicating the method used for variables selection. Four methods are avaible: recursive feature elimination (RFE) coupled with random forests ("RFERF") or logistic regressions ("RFEGlmnet"); another method using random forests ("VSURF"); and a method based on sparse partial least squares discriminate of the couples of the c

nant analysis ("sPLSDA").

MethodValidation

a charater indicating the resampling method: "cv" for cross-validation; "repeatedcv"

for repeated cross-validation; and "LOOCV" for leave-one-out cross-validation.

NumberCV a numeric value indicating K-folds for cross-validation. Not used for VSURF

method.

RepeatsCV a numeric value indication the number of repeat(s) for K-folds for cross-validation

or repeated cross-validation. Not used for VSURF method.

PreProcessing a vector indicating the method(s) used to pre-process the mass spectra in X:

centering (center), scaling (scale), eliminating near zero variance predictors

(nzv), or correlated predictors (corr).

Metric a character indicating metric to select the optimal model for RFE algorithm,

possibles metrics are the "Kappa" coefficient or "Accuracy". This argument is not used for VSURF and sPLSDA methods which use the minimum mean out-of-bag (OOB) and balanced classification error rate (BER) metrics respectively.

Sampling a charater indicating an optional subsampling method to handle imbalanced

datasets: subsampling methods are either "up", "down" or "smote".

Sizes a numeric vector indicating the number of variables to select. Not used for

VSURF method. For the RFERF and RFEGlmnet methods, the final number of selected variables is the one giving the highest average Metric ("Accruracy" or

"Kappa") on the folds used for cross-validation. It is thus bounded by NumberCV*max(Sizes).

The sPLSDA method selects variables from the ones kept in latent components of the model using an automatic choice of the number of components (when the

balanced classification error rate (BER) reaches a plateau).

Ntree a numeric value indicating the number of trees in each forest, only used if

MethodSelection = "VSURF" (1000 by default).

ncomp.max a positive Integer indicating the maximum number of components that can

be included in the sPLS-DA model (10 by default).

threshold a numeric value corresponding to a threshold used for the optimal selection of

the number of components included in the sPLS-DA model (0.01 by default). When the number of components increases and the balanced classification error rate (BER) does not change anymore, we keep the minimal number where the BER reaches a plateau (i.e. when BER(N)-BER(N+1)<threshold, we keep N).

If a plateau is not reached, ncomp. max components are selected.

22 Selection Var

Details

See rfe in the caret R package, VSURF in the VSURF R package and splsda in the mixOmics R package for details.

For Sampling methods available for unbalanced data: "up" corresponds to the up-sampling method which consists of random sampling (with replacement) so that the minority class is the same size as the majority class; "down" corresponds to the down-sampling method randomly which consists of random sampling (without replacement) of the majority class so that their class frequencies match the minority class; "smote" corresponds to the Synthetic Minority Over sampling Technique (SMOTE) specific algorithm for data augmentation which consist of creates new data from minority class using the K Nearest Neighbor algorithm.

Value

A list composed of:

sel_moz a vector with discriminant mass-over-chage values.

And of the results of the rfe function of the caret R package (methods RFERF and RFEGlmnet), or of the VSURF function of the VSURF R package (method VSURF).

For the sPLSDA method, it also returns the following items:

Raw_data a horizontal bar plot and containing the contribution of features on each component.

selected_variables

data frame with uniques features (selected variables to keep and containing the contribution of features in order to class samples). See plotLoadings in the mixOmics R package for details.

SelectionVarStat

Variable selection using statistical tests. Estimating the number of discriminant features (mass-over-chage values).

Description

This function performs statistical tests for each mass-over-chage value to determine which are discriminants between categories. Using the distribution of resulting p-values, it determines the expected number of discriminant features.

SelectionVarStat 25

Usage

Arguments

Υ

Χ	a numeric matrix corresponding to a library of mass spectra. Rows of X are
	the intensities of a mass spectrum measured on mass-over-charge values. The
	columns are mass-over-charge values.

a factor with a length equal to the number of rows in X and containing the categories of each mass spectrum in X.

a character among "anova", "kruskal", or "Limma" (default). It corresponds to the test used to know if the intensity measured at a mass-over-charge value is significantly different between categories. "anova" is for a classical ANOVA Fisher test, "kruskal" is for the Kruskal-Wallis test, "Limma" is for an ANOVA

Fisher test using the 1imma R package.

pi0.method a character among "abh", "st.spline", "st.boot", "langaas", "histo", "pounds",

"jiang", "slim". It corresponds to statistical methods used to estimate the proportion of true null hypotheses among the set of tested mass-over-charge values.

See the estim.pi0 function of th R package cp4p for details.

fdr a numeric corresponding to False Discovery Rate threshold used to determine

the differential mass-over-charge values. 0.05 by default.

Details

The SelectionVarStat function allows performing "quick" classification of mass-over-charge values. It tries to find all the mass-over-charge values (or the number of mass-over-charge values) that are discriminant between categories. This can conduct to select "correlated" (i.e. associated to intensities evolving similarly between categories) mass-over-charge values.

Value

A list composed of:

nb_to_sel a numeric value corresponding to an estimated number of mass-over-chage val-

ues where the intensities are significantly different between categories. It de-

pends on the statistical methods used in pi0.method.

NbEstimatedPeaks

a vector with discriminant mass-over-chage values resulting to the FDR threshold applied on the set of tested mass-over-charge values.

Signal Processing 27

SignalProcessing

Function performing post acquisition signal processing

Description

This function performs post acquisition signal processing for list of MassSpectrum objects using commonly used methods: transform intensities ("sqrt"), smoothing ("Wavelet"), remove baseline ("SNIP"), calibrate intensities ("TIC") and align spectra. Methods used are selected from the MALDIquant and MALDIrppa R packages.

Usage

```
SignalProcessing(x,
                 transformIntensity_method = "sqrt",
                 smoothing_method = "Wavelet",
                 removeBaseline_method = "SNIP",
                 removeBaseline_iterations = 25,
                 calibrateIntensity_method = "TIC",
                 alignSpectra_NoiseMethod = "MAD",
                 alignSpectra_method = "lowess",
                 alignSpectra_halfWs = 11,
                 alignSpectra_SN = 3,
                 tolerance_align = 0.002,
                 referenceSpectra = NULL,
                 minFrequency= 0.5,
                 binPeaks_method = "strict",
                 keepReferenceSpectra = FALSE,
                 ...)
```

Arguments

x a list of MassSpectrum objects (see MALDIquant R package).

transformIntensity_method

a character indicating the method used to transform intensities: "sqrt" by default. This function can be replaced by another mathematical function such as "log".

smoothing_method

a character indicating the smoothing methods used. By default, it performs undecimated Wavelet transform (UDWT) for list of MassSpectrum objects. This Smoothing method can be remplaced by "SavitzkyGolay" or "MovingAverage". See wavSmoothing in the MALDIrppa R package for details.

removeBaseline_method

a character indicating the method used to remove baseline. It uses "SNIP" method for list of MassSpectrum objects. This baseline estimation method can be remplaced "TopHat", "ConvexHull" or "median". See removeBaseline-methods of the MALDIquant R package for details.

28 SignalProcessing

removeBaseline_iterations

a numeric value indicting the number of iterations to remove baseline (by default = 25). See removeBaseline-methods of the MALDIquant R package for details

calibrateIntensity_method

a character indicating the intensities calibration method used ("TIC" method by default). This calibration method can be remplaced by "PQN" or "median". See calibrateIntensity-methods of the MALDIquant R package for details.

alignSpectra_NoiseMethod

a character indicating the noise estimation method. It uses "MAD" method for list of MassSpectrum objects. This noise estimation method estimation method can be remplaced "SuperSmoother". See estimateNoise-methods of the MALDIquant R package for details.

alignSpectra_method

a character indicating the warping method. It uses "lowess" method for list of MassSpectrum objects. This warping method method can be remplaced "linear", "quadratic" or "cubic". See determineWarpingFunctions of the MALDIquant R package for details.

alignSpectra_halfWs

a numeric value half window size to detect peaks (by default = 11). See detectPeaks-methods of the MALDIquant R package for details.

alignSpectra_SN

a numeric value indicating the signal-to-noise ratio used to detect peaks (by default = 3). See detectPeaks-methods of the MALDIquant R package for details.

tolerance_align

a numeric value indicating a maximal relative deviation of a peak position (mass) to be considered as identical in ppm (by default = 0.002). See determineWarpingFunctions of the MALDIquant R package for details.

referenceSpectra

a MassPeaks reference spectrum for alignment of the sample(s). If this reference spectrum is not provided, a reference spectrum is created using the minFrequency and binPeaks_method arguments. See referencePeaks of the MALDIquant R package for details.

minFrequency

a numeric minimum frequency for each peak over all analyzed spectra (by default = 0.5) for the creation of the reference spectrum. See referencePeaks of the MALDIquant R package for details.

binPeaks_method

a character indicating the method used to equalize masses for similar peaks for the creation of the reference spectrum. The "strict" method is used by default corresponding to a unique peak per bin from the same sample. This method can be remplaced by "relaxed" corresponding to multiple peaks per bin from the same sample. See binPeaks of the MALDIquant R package for more details.

keepReferenceSpectra

a logical value indicating if the created reference spectrum is returned by the function (FALSE, default).

SignalProcessing 29

other arguments from MALDIrppa packages for the wavSmoothing function such as n.levels (corresponding to the depth of the decomposition for the wavelet function). See wavSmoothing of the MALDIrppa R package for details.

Details

The SignalProcessing function provides an analysis pipeline for MassSpectrum objects including intensity transformation, smoothing, removing baseline.

The Wavelet method relies on the wavShrink function of the wmtsa package and its dependencies (now archived by CRAN). The original C code by William Constantine and Keith L. Davidson, in turn including copyrighted routines by Insightful Corp., has been revised and included into MALDIrppa for the method to work.

All the methods used for SignalProcessing functions are selected from MALDIquant and MALDIrppa packages.

Value

A list of modified MassSpectrum objects (see MALDIquant R package) according to chosen arguments. If the argument referenceSpectra is not completed and the argument keepReferenceSpectra is TRUE, a list containing the MassSpectrum objects modified named "spectra" and the created reference spectrum named "RefS" is returned.
