

Package ‘backbone’

October 18, 2022

Type Package

Title Extracts the Backbone from Graphs

Version 2.1.1

Description An implementation of methods for extracting an unweighted unipartite graph (i.e. a backbone) from an unweighted unipartite graph, a weighted unipartite graph, the projection of an unweighted bipartite graph , or the projection of a weighted bipartite graph (Neal, 2022 <[doi:10.1371/journal.pone.0269137](https://doi.org/10.1371/journal.pone.0269137)>).

backbone

backbone: Extracts the Backbone from Graphs

Description

Provides methods for extracting from an unweighted and sparse subgraph (i.e., a backbone) that contains only the most "important" edges in a weighted bipartite projection, a non-projection weighted network, or an unweighted network.

Available backbone extraction functions include:

- For weighted bipartite projections of weighted bipartite networks: `osdsm()`.
- For weighted bipartite projections of binary bipartite networks: `fixedfill()`, `fixedrow()`, `fixedcol()`, `sdsm()`, and `fdsm()`.
- For non-projection weighted networks: `global()`, `disparity()`.
- For unweighted networks: `sparsify()`, `sparsify.with.skeleton()`, `sparsify.with.gspar()`, `sparsify.with.lspar()`, `sparsify.with.simmelian()`, `sparsify.with.jaccard()`, `sparsify.with.meetmin()`, `sparsify.with.geometric()`, `sparsify.with.hypergeometric()`, `sparsify.with.localdegree()`, `sparsify.with.quadrilateral()`.

- For all networks: `backbone.suggest()` will examine the data and suggest an appropriate backbone function

The package also includes some utility functions:

- `fastball()` - Fast marginal-preserving randomization of binary matrices
- `bicm()` - Compute probabilities under the bipartite configuration model

For additional documentation and background on the package functions, see `vignette("backbone")`. For updates, papers, presentations, and other backbone news, please see www.rbackbone.net

backbone.extract	<i>Extracts a backbone network from a backbone object</i>
------------------	---

Description

`backbone.extract` returns a binary or signed adjacency matrix containing the backbone that retains only the significant edges.

Usage

```
backbone.extract(
  bb.object,
  signed = FALSE,
  alpha = 0.05,
  mtc = "none",
  class = bb.object$class,
  narrative = FALSE
)
```

Arguments

<code>bb.object</code>	backbone: backbone S3 class object.
<code>signed</code>	Boolean: TRUE for a signed backbone, FALSE for a binary backbone (see details)
<code>alpha</code>	Real: significance level of hypothesis test(s)
<code>mtc</code>	string: type of Multiple Test Correction to be applied; can be any method allowed by <code>p.adjust</code> .
<code>class</code>	string: the class of the returned backbone graph, one of <code>c("matrix", "sparseMatrix", "igraph", "edgelist")</code> , converted via <code>tomatrix</code> .
<code>narrative</code>	boolean: TRUE if suggested text & citations should be displayed.

Details

The "backbone" S3 class object is composed of (1) the weighted graph as a matrix, (2) upper-tail p-values as a matrix, (3, if signed = TRUE) lower-tail p-values as a matrix, (4, if present) node attributes as a dataframe, and (5) several properties of the original graph and backbone model

When signed = FALSE, a one-tailed test (is the weight stronger) is performed for each edge with a non-zero weight. It yields a backbone that preserves edges whose weights are significantly *stronger* than expected in the chosen null model. When signed = TRUE, a two-tailed test (is the weight stronger or weaker) is performed for each every pair of nodes. It yields a backbone that contains positive edges for edges whose weights are significantly *stronger*, and negative edges for edges whose weights are significantly *weaker*, than expected in the chosen null model. *NOTE: Before v2.0.0, all significance tests were two-tailed and zero-weight edges were evaluated.*

Value

backbone graph: Binary or signed backbone graph of class given in parameter class.

Examples

```
#A binary bipartite network of 30 agents & 75 artifacts; agents form three communities
B <- rbind(cbind(matrix(rbinom(250,1,.8),10),
  matrix(rbinom(250,1,.2),10),
  matrix(rbinom(250,1,.2),10)),
  cbind(matrix(rbinom(250,1,.2),10),
  matrix(rbinom(250,1,.8),10),
  matrix(rbinom(250,1,.2),10)),
  cbind(matrix(rbinom(250,1,.2),10),
  matrix(rbinom(250,1,.2),10),
  matrix(rbinom(250,1,.8),10)))

backbone.object <- fixedrow(B, alpha = NULL)
bb <- backbone.extract(backbone.object, alpha = 0.05)
```

backbone.suggest *Suggest a backbone model*

Description

backbone.suggest suggests and optionally runs an appropriate backbone model for a graph object.

Usage

```
backbone.suggest(G, s = NULL)
```

Arguments

- G graph: A graph represented in an object of class matrix, sparse [Matrix](#), dataframe, or [igraph](#).
- s numeric: If provided, a backbone is extracted using this value as the significance level or sparsification parameter.

Value

If `s == NULL`: `NULL`, but a message is displayed with a suggested model. If $0 \leq s \leq 1$: A binary backbone graph in the same class as `G`, obtained by extracting the backbone at the `s` significance level (if a statistical model is suggested) or using sparsification parameter `s` (if a sparsification model is suggested). The code used to perform the extraction, and suggested manuscript text are displayed.

Examples

```
M <- matrix(runif(100),10,10) #A random weighted, directed graph
backbone <- backbone.suggest(M)
backbone <- backbone.suggest(M, s = 0.05)
```

bicm

Bipartite Configuration Model

Description

`bicm` estimates cell probabilities under the bipartite configuration model

Usage

```
bicm(M, fitness = FALSE, tol = 1e-08, max_steps = 200, ...)
```

Arguments

<code>M</code>	matrix: a binary matrix
<code>fitness</code>	boolean: <code>FALSE</code> returns a matrix of probabilities, <code>TRUE</code> returns a list of row and column fitnesses only
<code>tol</code>	numeric, tolerance of algorithm
<code>max_steps</code>	numeric, number of times to run loglikelihood_prime_bicm algorithm
<code>...</code>	optional arguments

Details

Given a binary matrix \mathbf{M} , the Bipartite Configuration Model (BiCM; Saracco et. al. 2015) returns a valued matrix \mathbf{B} in which B_{ij} is the *approximate* probability that $M_{ij} = 1$ in the space of all binary matrices with the same row and column marginals as \mathbf{M} . The BiCM yields the closest approximations of the true probabilities compared to other estimation methods (Neal et al., 2021), and is used by `sdsm()` to extract the backbone of a bipartite projection using the stochastic degree sequence model.

Matrix **M** is "conforming" if no rows and no columns contain only zeros or only ones. If **M** is conforming, then `bicm()` is faster. Additionally, if `fitness = TRUE`, then `bicm()` returns a list of row and column fitnesses, which requires less memory. Given the *i*th row's fitness R_i and the *j*th column's fitness R_j , the entry B_{ij} in the probability matrix can be computed as $R_i \times R_j / (1 + (R_i \times R_j))$.

Matrix **M** is "non-conforming" if any rows or any columns contain only zeros or only ones. If **M** is non-conforming, then `bicm()` is slower and will only return a probability matrix.

Value

a matrix of probabilities or a list of fitnesses

Examples

```
M <- matrix(c(0,0,1,0,1,0,1,0,1),3,3) #A binary matrix
bicm(M)
```

disparity

Extract backbone using the Disparity Filter

Description

`disparity` extracts the backbone of a weighted network using the Disparity Filter.

Usage

```
disparity(
  W,
  alpha = 0.05,
  signed = FALSE,
  mtc = "none",
  class = "original",
  narrative = FALSE
)
```

Arguments

W	A weighted unipartite graph, as: (1) an adjacency matrix in the form of a matrix or sparse <code>Matrix</code> ; (2) an edgelist in the form of a three-column dataframe; (3) an <code>igraph</code> object.
alpha	real: significance level of hypothesis test(s)
signed	boolean: TRUE for a signed backbone, FALSE for a binary backbone (see details)
mtc	string: type of Multiple Test Correction to be applied; can be any method allowed by <code>p.adjust</code> .
class	string: the class of the returned backbone graph, one of <code>c("original", "matrix", "Matrix", "igraph", "edgelist")</code> . If "original", the backbone graph returned is of the same class as W.
narrative	boolean: TRUE if suggested text & citations should be displayed.

Details

The `disparity` function applies the disparity filter (Serrano et al., 2009), which compares an edge's weight to its expected weight if a node's total degree was uniformly distributed across all its edges. The graph may be directed or undirected, however the edge weights must be positive.

When `signed = FALSE`, a one-tailed test (is the weight stronger) is performed for each edge with a non-zero weight. It yields a backbone that preserves edges whose weights are significantly *stronger* than expected in the chosen null model. When `signed = TRUE`, a two-tailed test (is the weight stronger or weaker) is performed for each every pair of nodes. It yields a backbone that contains positive edges for edges whose weights are significantly *stronger*, and negative edges for edges whose weights are significantly *weaker*, than expected in the chosen null model. *NOTE: Before v2.0.0, all significance tests were two-tailed and zero-weight edges were evaluated.*

If W is an unweighted bipartite graph, any rows and columns that contain only zeros or only ones are removed, then the global threshold is applied to its weighted bipartite projection.

Value

If `alpha != NULL`: Binary or signed backbone graph of class `class`.

If `alpha == NULL`: An S3 backbone object containing (1) the weighted graph as a matrix, (2) upper-tail p-values as a matrix, (3, if `signed = TRUE`) lower-tail p-values as a matrix, (4, if present) node attributes as a dataframe, and (5) several properties of the original graph and backbone model, from which a backbone can subsequently be extracted using `backbone.extract()`.

              10,1,1,0,1,0,0,0,0,0,
              10,1,1,1,0,0,0,0,0,0,
              75,0,0,0,0,0,100,100,100,100,
              0,0,0,0,0,100,0,10,10,10,
              0,0,0,0,0,100,10,0,10,10,
              0,0,0,0,0,100,10,10,0,10,
              0,0,0,0,0,100,10,10,10,0),10)

net <- igraph::graph_from_adjacency_matrix(net, mode = "undirected", weighted = TRUE)
plot(net, edge.width = sqrt(igraph::E(net)$weight)) #A stronger clique & a weaker clique

strong <- igraph::delete.edges(net, which(igraph::E(net)$weight < mean(igraph::E(net)$weight)))
plot(strong) #A backbone of stronger-than-average edges ignores the weaker clique

bb <- disparity(net, alpha = 0.05, narrative = TRUE) #A disparity backbone...
plot(bb) #...preserves edges at multiple scales
```

fastball

Randomize a binary matrix using the fastball algorithm

Description

fastball randomizes a binary matrix, preserving the row and column sums

Usage

```
fastball(M, trades = 5 * nrow(M))
```

Arguments

M	matrix: a binary matrix (see details)
trades	integer: number of trades; the default is 5R trades (approx. mixing time)

Details

Given a matrix M, fastball randomly samples a new matrix from the space of all matrices with the same row and column sums as M.

Value

matrix: A random binary matrix with same row sums and column sums as M.

References

Godard, Karl and Neal, Zachary P. 2022. fastball: A fast algorithm to sample bipartite graphs with fixed degree sequences. *arXiv:2112.04017*

Examples

```
M <- matrix(rbinom(200,1,0.5),10,20) #A random 10x20 binary matrix
Mrand <- fastball(M) #Random matrix with same row and column sums
```

fdsm *Extract backbone using the Fixed Degree Sequence Model*

Description

fdsm extracts the backbone of a bipartite projection using the Fixed Degree Sequence Model.

Usage

```
fdsm(
  B,
  alpha = 0.05,
  trials = NULL,
  signed = FALSE,
  mtc = "none",
  class = "original",
  narrative = FALSE,
  progress = TRUE,
  ...
)
```

Arguments

B	An unweighted bipartite graph, as: (1) an incidence matrix in the form of a matrix or sparse Matrix ; (2) an edgelist in the form of a two-column dataframe; (3) an igraph object.
alpha	real: significance level of hypothesis test(s)
trials	numeric: the number of bipartite graphs generated to approximate the edge weight distribution. If NULL, the number of trials is selected based on alpha (see details)
signed	boolean: TRUE for a signed backbone, FALSE for a binary backbone (see details)
mtc	string: type of Multiple Test Correction to be applied; can be any method allowed by p.adjust .
class	string: the class of the returned backbone graph, one of c("original", "matrix", "Matrix", "igraph", "edgelist"). If "original", the backbone graph returned is of the same class as B.

narrative	boolean: TRUE if suggested text & citations should be displayed.
progress	boolean: TRUE if the progress of Monte Carlo trials should be displayed.
...	optional arguments

Details

The `fdsm` function compares an edge's observed weight in the projection $B \times t(B)$ to the distribution of weights expected in a projection obtained from a random bipartite network where both the row vertex degrees and column vertex degrees are *exactly* fixed at their values in B . It uses the `fastball()` algorithm to generate random bipartite matrices with given row and column vertex degrees.

When `signed = FALSE`, a one-tailed test (is the weight stronger) is performed for each edge with a non-zero weight. It yields a backbone that preserves edges whose weights are significantly *stronger* than expected in the chosen null model. When `signed = TRUE`, a two-tailed test (is the weight stronger or weaker) is performed for each every pair of nodes. It yields a backbone that contains positive edges for edges whose weights are significantly *stronger*, and negative edges for edges whose weights are significantly *weaker*, than expected in the chosen null model. *NOTE: Before v2.0.0, all significance tests were two-tailed and zero-weight edges were evaluated.*

The p-values used to evaluate the statistical significance of each edge are computed using Monte Carlo methods. The number of `trials` performed affects the precision of these p-values, and the confidence that a given p-value is less than the desired alpha level. Because these p-values are proportions (i.e., the proportion of times an edge is weaker/stronger in the projection of a random bipartite graphs), evaluating the statistical significance of an edge is equivalent to comparing a proportion (the p-value) to a known proportion (alpha). When `trials = NULL`, the `power.prop.test` function is used to estimate the required number of trials to make such a comparison with a alpha type-I error rate, (1-alpha) power, and when the riskiest p-value being evaluated is at least 5% smaller than alpha. When any `mtc` correction is applied, for simplicity this estimation is based on a conservative Bonferroni correction.

Value

If `alpha != NULL`: Binary or signed backbone graph of class `class`.

If `alpha == NULL`: An S3 backbone object containing (1) the weighted graph as a matrix, (2) upper-tail p-values as a matrix, (3, if `signed = TRUE`) lower-tail p-values as a matrix, (4, if present) node attributes as a dataframe, and (5) several properties of the original graph and backbone model, from which a backbone can subsequently be extracted using `backbone.extract()`.

```

fixedcol

*Extract backbone using the Fixed Column Model***Description**

fixedcol extracts the backbone of a bipartite projection using the Fixed Column Model.

Usage

```
fixedcol(
  B,
  alpha = 0.05,
  signed = FALSE,
  mtc = "none",
  class = "original",
  narrative = FALSE
)
```

Arguments

B	An unweighted bipartite graph, as: (1) an incidence matrix in the form of a matrix or sparse Matrix ; (2) an edgelist in the form of a two-column dataframe; (3) an igraph object.
alpha	real: significance level of hypothesis test(s)
signed	boolean: TRUE for a signed backbone, FALSE for a binary backbone (see details)
mtc	string: type of Multiple Test Correction to be applied; can be any method allowed by p.adjust .

class	string: the class of the returned backbone graph, one of c("original", "matrix", "Matrix", "igraph", "edgelist"). If "original", the backbone graph returned is of the same class as B.
narrative	boolean: TRUE if suggested text & citations should be displayed.

Details

This `fixedcol` function compares an edge's observed weight in the projection $B * t(B)$ to the distribution of weights expected in a projection obtained from a random bipartite graph where the *column* vertex degrees are fixed but the row vertex degrees are allowed to vary.

When `signed = FALSE`, a one-tailed test (is the weight stronger) is performed for each edge with a non-zero weight. It yields a backbone that preserves edges whose weights are significantly *stronger* than expected under the null model. When `signed = TRUE`, a two-tailed test (is the weight stronger or weaker) is performed for each every pair of nodes. It yields a backbone that contains positive edges for edges whose weights are significantly *stronger*, and negative edges for edges whose weights are significantly *weaker*, than expected in the chosen null model. *NOTE: Before v2.0.0, all significance tests were two-tailed and zero-weight edges were evaluated.*

Value

If `alpha != NULL`: Binary or signed backbone graph of class `class`.

If `alpha == NULL`: An S3 backbone object containing (1) the weighted graph as a matrix, (2) upper-tail p-values as a matrix, (3, if `signed = TRUE`) lower-tail p-values as a matrix, (4, if present) node attributes as a dataframe, and (5) several properties of the original graph and backbone model, from which a backbone can subsequently be extracted using `backbone.extract()`.

plot(bb) #...is sparse with clear communities

```

fixedfill

Extract backbone using the Fixed Fill Model

Description

fixedfill extracts the backbone of a bipartite projection using the Fixed Fill Model.

Usage

```

fixedfill(
  B,
  alpha = 0.05,
  signed = FALSE,
  mtc = "none",
  class = "original",
  narrative = FALSE
)

```

Arguments

B	An unweighted bipartite graph, as: (1) an incidence matrix in the form of a matrix or sparse Matrix ; (2) an edgelist in the form of a two-column dataframe; (3) an igraph object.
alpha	real: significance level of hypothesis test(s)
signed	boolean: TRUE for a signed backbone, FALSE for a binary backbone (see details)
mtc	string: type of Multiple Test Correction to be applied; can be any method allowed by p.adjust .
class	string: the class of the returned backbone graph, one of c("original", "matrix", "Matrix", "igraph", "edgelist"). If "original", the backbone graph returned is of the same class as B.
narrative	boolean: TRUE if suggested text & citations should be displayed.

Details

The fixedfill function compares an edge's observed weight in the projection $B * t(B)$ to the distribution of weights expected in a projection obtained from a random bipartite graph where the number of edges present (i.e., the number of cells *filled* with a 1) is equal to the number of edges in B. When B is large, this function may be impractically slow and may return a backbone object that contains NaN values.

When `signed = FALSE`, a one-tailed test (is the weight stronger) is performed for each edge with a non-zero weight. It yields a backbone that preserves edges whose weights are significantly *stronger* than expected under the null model. When `signed = TRUE`, a two-tailed test (is the weight stronger or weaker) is performed for each every pair of nodes. It yields a backbone that contains positive edges for edges whose weights are significantly *stronger*, and negative edges for edges whose weights are significantly *weaker*, than expected in the chosen null model. *NOTE: Before v2.0.0, all significance tests were two-tailed and zero-weight edges were evaluated.*

Value

If `alpha != NULL`: Binary or signed backbone graph of class `class`.

If `alpha == NULL`: An S3 backbone object containing (1) the weighted graph as a matrix, (2) upper-tail p-values as a matrix, (3, if `signed = TRUE`) lower-tail p-values as a matrix, (4, if present) node attributes as a dataframe, and (5) several properties of the original graph and backbone model, from which a backbone can subsequently be extracted using `backbone.extract()`.

Examples

```
#A binary bipartite network of 30 agents & 75 artifacts; agents form three communities
B <- rbind(cbind(matrix(rbinom(250,1,.8),10),
  matrix(rbinom(250,1,.2),10),
  matrix(rbinom(250,1,.2),10)),
  cbind(matrix(rbinom(250,1,.2),10),
  matrix(rbinom(250,1,.8),10),
  matrix(rbinom(250,1,.2),10)),
  cbind(matrix(rbinom(250,1,.2),10),
  matrix(rbinom(250,1,.2),10),
  matrix(rbinom(250,1,.8),10)))

P <- B*%t(B) #An ordinary weighted projection...
plot(igraph::graph_from_adjacency_matrix(P, mode = "undirected",
  weighted = TRUE, diag = FALSE)) #...is a dense hairball

bb <- fixedfill(B, alpha = 0.05, narrative = TRUE, class = "igraph") #A fixedfill backbone...
plot(bb) #...is sparse with clear communities
```

fixedrow

*Extract backbone using the Fixed Row Model***Description**

fixedrow extracts the backbone of a bipartite projection using the Fixed Row Model.

Usage

```
fixedrow(
  B,
  alpha = 0.05,
  signed = FALSE,
  mtc = "none",
  class = "original",
  narrative = FALSE
)
```

Arguments

B	An unweighted bipartite graph, as: (1) an incidence matrix in the form of a matrix or sparse Matrix ; (2) an edgelist in the form of a two-column dataframe; (3) an igraph object.
alpha	real: significance level of hypothesis test(s)
signed	boolean: TRUE for a signed backbone, FALSE for a binary backbone (see details)
mtc	string: type of Multiple Test Correction to be applied; can be any method allowed by p.adjust .
class	string: the class of the returned backbone graph, one of c("original", "matrix", "Matrix", "igraph", "edgelist"). If "original", the backbone graph returned is of the same class as B.
narrative	boolean: TRUE if suggested text & citations should be displayed.

Details

The fixedrow function compares an edge's observed weight in the projection $B * t(B)$ to the distribution of weights expected in a projection obtained from a random bipartite graph where the *row* vertex degrees are fixed but the column vertex degrees are allowed to vary.

When signed = FALSE, a one-tailed test (is the weight stronger) is performed for each edge with a non-zero weight. It yields a backbone that preserves edges whose weights are significantly *stronger* than expected under the null model. When signed = TRUE, a two-tailed test (is the weight stronger or weaker) is performed for each every pair of nodes. It yields a backbone that contains positive edges for edges whose weights are significantly *stronger*, and negative edges for edges whose weights are significantly *weaker*, than expected in the chosen null model. *NOTE: Before v2.0.0, all significance tests were two-tailed and zero-weight edges were evaluated.*

Value

If `alpha != NULL`: Binary or signed backbone graph of class `class`.

If `alpha == NULL`: An S3 backbone object containing (1) the weighted graph as a matrix, (2) upper-tail p-values as a matrix, (3, if `signed = TRUE`) lower-tail p-values as a matrix, (4, if present) node attributes as a dataframe, and (5) several properties of the original graph and backbone model, from which a backbone can subsequently be extracted using `backbone.extract()`.

plot(bb) #...is sparse with clear communities
```

 global

Compute global threshold backbone

Description

`global` extracts the backbone of a weighted network using a global threshold

Usage

```
global(
  W,
  upper = 0,
  lower = NULL,
```

```

    keepzeros = TRUE,
    class = "original",
    narrative = FALSE
  )

```

Arguments

W	A weighted unipartite graph, as: (1) an adjacency matrix in the form of a matrix or sparse <code>Matrix</code> , or dataframe; (2) an edgelist in the form of a three-column dataframe; (3) an <code>igraph</code> object.
upper	real, FUN, or NULL: upper threshold value or function that evaluates to an upper threshold value.
lower	real, FUN, or NULL: lower threshold value or function that evaluates to a lower threshold value.
keepzeros	boolean: TRUE if zero-weight edges in W should be excluded from (i.e. also be zero in) the backbone
class	string: the class of the returned backbone graph, one of c("original", "matrix", "Matrix", "igraph", "edgelist"). If "original", the backbone graph returned is of the same class as W.
narrative	boolean: TRUE if suggested text & citations should be displayed.

Details

The `global` function retains a edge in the backbone if its weight exceeds `upper`. If a lower threshold is also specified, it returns a signed backbone in which edge weights are set to 1 if above the given upper threshold, set to -1 if below the given lower threshold, and set to 0 otherwise.

If W is an unweighted bipartite graph, any rows and columns that contain only zeros or only ones are removed, then the global threshold is applied to its weighted bipartite projection.

Value

Binary or signed backbone graph of class given in parameter `class`.

osdsm	<i>Extract backbone using the Ordinal Stochastic Degree Sequence Model</i>
-------	--

Description

osdsm extracts the backbone of a bipartite projection using the Ordinal Stochastic Degree Sequence Model.

Usage

```

osdsm(
  B,
  alpha = 0.05,
  trials = NULL,
  signed = FALSE,
  mtc = "none",
  class = "original",
  narrative = FALSE,
  progress = TRUE
)

```

Arguments

B	An ordinally weighted bipartite graph, as: (1) an incidence matrix in the form of a matrix or sparse Matrix ; (2) an edgelist in the form of a three-column dataframe; (3) an igraph object.
alpha	real: significance level of hypothesis test(s)
trials	integer: the number of bipartite graphs generated to approximate the edge weight distribution. If NULL, the number of trials is selected based on alpha (see details)
signed	boolean: TRUE for a signed backbone, FALSE for a binary backbone (see details)
mtc	string: type of Multiple Test Correction to be applied; can be any method allowed by p.adjust .
class	string: the class of the returned backbone graph, one of c("original", "matrix", "Matrix", "igraph", "edgelist"). If "original", the backbone graph returned is of the same class as B.
narrative	boolean: TRUE if suggested text & citations should be displayed.
progress	boolean: TRUE if the progress of Monte Carlo trials should be displayed.

Details

The `osdsm` function compares an edge's observed weight in the projection $B \times t(B)$ to the distribution of weights expected in a projection obtained from a random bipartite network where both the rows and the columns contain approximately the same number of each value. The edges in B must be integers, and are assumed to represent an ordinal-level measure such as a Likert scale that starts at 0.

When `signed = FALSE`, a one-tailed test (is the weight stronger) is performed for each edge with a non-zero weight. It yields a backbone that preserves edges whose weights are significantly *stronger* than expected in the chosen null model. When `signed = TRUE`, a two-tailed test (is the weight stronger or weaker) is performed for each every pair of nodes. It yields a backbone that contains positive edges for edges whose weights are significantly *stronger*, and negative edges for edges whose weights are significantly *weaker*, than expected in the chosen null model. *NOTE: Before v2.0.0, all significance tests were two-tailed and zero-weight edges were evaluated.*

The p-values used to evaluate the statistical significance of each edge are computed using Monte Carlo methods. The number of `trials` performed affects the precision of these p-values, and the confidence that a given p-value is less than the desired alpha level. Because these p-values are proportions (i.e., the proportion of times an edge is weaker/stronger in the projection of a random bipartite graphs), evaluating the statistical significance of an edge is equivalent to comparing a proportion (the p-value) to a known proportion (alpha). When `trials = NULL`, the `power.prop.test` function is used to estimate the required number of trials to make such a comparison with a alpha type-I error rate, (1-alpha) power, and when the riskiest p-value being evaluated is at least 5% smaller than alpha. When any `mtc` correction is applied, for simplicity this estimation is based on a conservative Bonferroni correction.

Value

If `alpha != NULL`: Binary or signed backbone graph of class `class`.

If `alpha == NULL`: An S3 backbone object containing (1) the weighted graph as a matrix, (2) upper-tail p-values as a matrix, (3, if `signed = TRUE`) lower-tail p-values as a matrix, (4, if present) node attributes as a dataframe, and (5) several properties of the original graph and backbone model, from which a backbone can subsequently be extracted using `backbone.extract()`.

plot(bb) #...is sparse with clear communities

```

pb

Poisson binomial distribution function

Description

pb computes the poisson binomial distribution function using the refined normal approximation.

Usage

```
pb(k, p, lowertail = TRUE)
```

Arguments

k	numeric: value where the pdf should be evaluated
p	vector: vector of success probabilities
lowertail	boolean: If TRUE return both upper & lower tail probabilities, if FALSE return only upper tail probability

Details

The Refined Normal Approximation (RNA) offers a close approximation when $\text{length}(p)$ is large (Hong, 2013). This function is based on `ppoibin()` from the `poibin` package.

Value

vector, length 2: The first value (if `lower = TRUE`) is the lower tail probability, the probability of observing k or fewer successes when each trial has probability p of success. The second value is the upper tail probability, the probability of observing k or more successes when each trial has probability p of success.

sdsdm

*Extract backbone using the Stochastic Degree Sequence Model***Description**

sdsdm extracts the backbone of a bipartite projection using the Stochastic Degree Sequence Model.

Usage

```
sdsdm(
  B,
  alpha = 0.05,
  signed = FALSE,
  mtc = "none",
  class = "original",
  narrative = FALSE,
  ...
)
```

Arguments

B	An unweighted bipartite graph, as: (1) an incidence matrix in the form of a matrix or sparse Matrix ; (2) an edgelist in the form of a two-column dataframe; (3) an igraph object.
alpha	real: significance level of hypothesis test(s)
signed	boolean: TRUE for a signed backbone, FALSE for a binary backbone (see details)
mtc	string: type of Multiple Test Correction to be applied; can be any method allowed by p.adjust .
class	string: the class of the returned backbone graph, one of c("original", "matrix", "Matrix", "igraph", "edgelist"). If "original", the backbone graph returned is of the same class as B.
narrative	boolean: TRUE if suggested text & citations should be displayed.
...	optional arguments

Details

The sdsdm function compares an edge's observed weight in the projection $B \times t(B)$ to the distribution of weights expected in a projection obtained from a random bipartite network where both the row vertex degrees and column vertex degrees are *approximately* fixed at their values in B. It uses the Bipartite Configuration Model [bicum](#) to compute probabilities for the Poisson binomial distribution.

When `signed = FALSE`, a one-tailed test (is the weight stronger) is performed for each edge with a non-zero weight. It yields a backbone that preserves edges whose weights are significantly *stronger* than expected in the chosen null model. When `signed = TRUE`, a two-tailed test (is the weight stronger or weaker) is performed for each every pair of nodes. It yields a backbone that contains

positive edges for edges whose weights are significantly *stronger*, and negative edges for edges whose weights are significantly *weaker*, than expected in the chosen null model. *NOTE: Before v2.0.0, all significance tests were two-tailed and zero-weight edges were evaluated.*

Value

If alpha != NULL: Binary or signed backbone graph of class class.

If alpha == NULL: An S3 backbone object containing (1) the weighted graph as a matrix, (2) upper-tail p-values as a matrix, (3, if signed = TRUE) lower-tail p-values as a matrix, (4, if present) node attributes as a dataframe, and (5) several properties of the original graph and backbone model, from which a backbone can subsequently be extracted using `backbone.extract()`.

```

sparsify

*Extract the backbone from a network using a sparsification model***Description**

A generic function to extract the backbone of an undirected, unipartite network using a sparsification model described by a combination of an edge scoring metric, a edge score normalization, and an edge score filter.

Usage

```
sparsify(
  U,
  s,
  escore = "original",
  normalize,
  filter,
  umst = FALSE,
  class = "original",
  narrative = FALSE
)
```

Arguments

U	An unweighted unipartite graph, as: (1) an adjacency matrix in the form of a matrix or sparse Matrix ; (2) an edgelist in the form of a two-column dataframe; (3) an igraph object.
s	numeric: Sparsification parameter
escore	string: Method for scoring edges' importance
normalize	string: Method for normalizing edge scores
filter	string: Type of filter to apply
umst	boolean: TRUE if the backbone should include the union of minimum spanning trees, to ensure connectivity
class	string: the class of the returned backbone graph, one of c("original", "matrix", "Matrix", "igraph", "edgelist"). If "original", the backbone graph returned is of the same class as U.
narrative	boolean: TRUE if suggested text & citations should be displayed.

Details

The escore parameter determines how an unweighted edge's importance is calculated. Unless noted below, scores are symmetric and larger values represent more important edges. There are 10 options for assigning an edge's score; when escore =

- random: a random number drawn from a uniform distribution

- `betweenness`: edge betweenness
- `triangles`: number of triangles that include the edge
- `jaccard`: jaccard coefficient of the neighborhoods of an edge's endpoints, or alternatively, triangles normalized by the size of the union of the endpoints neighborhoods
- `quadrangles`: number of quadrangles that include the edge
- `quadrilateral_embeddedness`: geometric mean normalization of quadrangles
- `degree`: degree of neighbor to which an edge is adjacent (asymmetric)
- `meetmin`: triangles normalized by the smaller of the endpoints' neighborhoods' sizes
- `geometric`: triangles normalized by the product of the endpoints' neighborhoods' sizes
- `hypergeometric`: probability of the edge being included at least as many triangles if edges were random, given the size of the endpoints' neighborhoods (smaller is more important)

The `normalize` parameter determines whether edge scores are normalized. There are three options; when `normalize =`

- `none`: no normalization is performed
- `rank`: scores are normalized by neighborhood rank, such that the strongest edge in a node's neighborhood is ranked 1 (asymmetric)
- `embeddedness`: scores are normalized using the maximum Jaccard coefficient of the top k-ranked neighbors of each endpoint, for all k

The `filter` parameter determines how edges are filtered based on their (normalized) edge scores. There are three options; when `filter =`

- `threshold`: Edges with scores more important than `s` are retained in the backbone
- `proportion`: Specifies the proportion of most important edges to retain in the backbone
- `degree`: Retains each node's d^s most important edges, where `d` is the node's degree (requires that `normalize = "rank"`)

Specific combinations of `escore`, `normalize`, `filter`, and `umst` correspond to specific sparsification models in the literature, and are available via the following wrapper functions: `sparsify.with.skeleton()`, `sparsify.with.gspar()`, `sparsify.with.lspar()`, `sparsify.with.simmelian()`, `sparsify.with.jaccard()`, `sparsify.with.meetmin()`, `sparsify.with.geometric()`, `sparsify.with.hypergeometric()`, `sparsify.with.localdegree()`, `sparsify.with.quadrilateral()`. See the documentation for these wrapper functions for more details and the associated citation.

Value

An unweighted, undirected, unipartite graph of class `class`.

Examples

```
U <- igraph::sbm.game(60, matrix(c(.75,.25,.25,.25,.75,.25,.25,.25,.75),3,3), c(20,20,20))
plot(U) #A hairball
sparse <- sparsify(U, s = 0.6, escore = "jaccard", normalize = "rank",
  filter = "degree", narrative = TRUE)
plot(sparse) #Clearly visible communities
```

sparsify.with.geometric

Extract Goldberg and Roth's (2003) Geometric backbone

Description

sparsify.with.geometric is a wrapper for `sparsify()` that extracts the geometric backbone described by Goldberg and Roth (2003). It is equivalent to `sparsify(escore = "geometric", normalize = "none", filter = "threshold", umst = FALSE)`.

Usage

```
sparsify.with.geometric(U, s, class = "original", narrative = FALSE)
```

Arguments

U	An unweighted unipartite graph, as: (1) an adjacency matrix in the form of a matrix or sparse <code>Matrix</code> ; (2) an edgelist in the form of a two-column dataframe; (3) an <code>igraph</code> object.
s	numeric: Sparsification threshold, $0 < s < 1$; larger values yield sparser graphs
class	string: the class of the returned backbone graph, one of <code>c("original", "matrix", "Matrix", "igraph", "edgelist")</code> . If "original", the backbone graph returned is of the same class as U.
narrative	boolean: TRUE if suggested text & citations should be displayed.

Value

An unweighted, undirected, unipartite graph of class `class`.

plot(sparse) #Clearly visible communities
```

sparsify.with.hypergeometric

Extract Goldberg and Roth's (2003) Hypergeometric backbone

Description

sparsify.with.hypergeometric is a wrapper for `sparsify()` that extracts the hypergeometric backbone described by Goldberg and Roth (2003). It is equivalent to `sparsify(escape = "hypergeometric", normalize = "none", filter = "threshold", umst = FALSE)`.

Usage

```
sparsify.with.hypergeometric(U, s, class = "original", narrative = FALSE)
```

Arguments

U	An unweighted unipartite graph, as: (1) an adjacency matrix in the form of a matrix or sparse <code>Matrix</code> ; (2) an edgelist in the form of a two-column dataframe; (3) an <code>igraph</code> object.
s	numeric: Sparsification threshold, $0 < s < 1$; smaller values yield sparser graphs
class	string: the class of the returned backbone graph, one of <code>c("original", "matrix", "Matrix", "igraph", "edgelist")</code> . If "original", the backbone graph returned is of the same class as U.
narrative	boolean: TRUE if suggested text & citations should be displayed.

Value

An unweighted, undirected, unipartite graph of class `class`.

References

package: Neal, Z. P. (2022). backbone: An R Package to Extract Network Backbones. *PLOS ONE*, *17*, e0269137. doi: [10.1371/journal.pone.0269137](https://doi.org/10.1371/journal.pone.0269137)

Examples

```
U <- igraph::sbm.game(60, matrix(c(.75,.25,.25,.25,.75,.25,.25,.25,.75),3,3), c(20,20,20))
plot(U) #A hairball
sparse <- sparsify.with.hypergeometric(U, s = 0.3, narrative = TRUE)
plot(sparse) #Clearly visible communities
```

sparsify.with.jaccard *Extract Goldberg and Roth's (2003) Jaccard backbone*

Description

sparsify.with.jaccard is a wrapper for `sparsify()` that extracts the jaccard backbone described by Goldberg and Roth (2003). It is equivalent to `sparsify(escape = "jaccard", normalize = "none", filter = "threshold", umst = FALSE)`.

Usage

```
sparsify.with.jaccard(U, s, class = "original", narrative = FALSE)
```

Arguments

U	An unweighted unipartite graph, as: (1) an adjacency matrix in the form of a matrix or sparse <code>Matrix</code> ; (2) an edgelist in the form of a two-column dataframe; (3) an <code>igraph</code> object.
s	numeric: Sparsification threshold, $0 < s < 1$; larger values yield sparser graphs
class	string: the class of the returned backbone graph, one of <code>c("original", "matrix", "Matrix", "igraph", "edgelist")</code> . If "original", the backbone graph returned is of the same class as U.
narrative	boolean: TRUE if suggested text & citations should be displayed.

Value

An unweighted, undirected, unipartite graph of class `class`.

Examples

```
U <- igraph::sbm.game(60, matrix(c(.75,.25,.25,.25,.75,.25,.25,.25,.75),3,3), c(20,20,20))
plot(U) #A hairball
sparse <- sparsify.with.jaccard(U, s = 0.3, narrative = TRUE)
plot(sparse) #Clearly visible communities
```

`sparsify.with.localdegree`*Extract Hamann et al.'s (2016) Local Degree backbone*

Description

`sparsify.with.localdegree` is a wrapper for `sparsify()` that extracts the local degree backbone described by Hamann et al. (2016). It is equivalent to `sparsify(escape = "degree", normalize = "rank", filter = "degree", umst = FALSE)`.

Usage

```
sparsify.with.localdegree(U, s, class = "original", narrative = FALSE)
```

Arguments

<code>U</code>	An unweighted unipartite graph, as: (1) an adjacency matrix in the form of a matrix or sparse <code>Matrix</code> ; (2) an edgelist in the form of a two-column dataframe; (3) an <code>igraph</code> object.
<code>s</code>	numeric: Sparsification exponent, $0 < s < 1$; smaller values yield sparser graphs
<code>class</code>	string: the class of the returned backbone graph, one of <code>c("original", "matrix", "Matrix", "igraph", "edgelist")</code> . If "original", the backbone graph returned is of the same class as <code>U</code> .
<code>narrative</code>	boolean: TRUE if suggested text & citations should be displayed.

Value

An unweighted, undirected, unipartite graph of class `class`.

Examples

```
U <- igraph::as.undirected(igraph::sample_pa(60, m = 3), mode = "collapse")
plot(U) #A hairball
sparse <- sparsify.with.localdegree(U, s = 0.3, narrative = TRUE)
plot(sparse) #Clearly visible hubs
```

sparsify.with.lspar *Extract Satuluri et al's (2011) L-spar backbone*

Description

sparsify.with.lspar is a wrapper for `sparsify()` that extracts the L-spar backbone described by Satuluri et al. (2011). It is equivalent to `sparsify(escore = "jaccard", normalize = "rank", filter = "degree", umst = FALSE)`.

Usage

```
sparsify.with.lspar(U, s, class = "original", narrative = FALSE)
```

Arguments

U	An unweighted unipartite graph, as: (1) an adjacency matrix in the form of a matrix or sparse <code>Matrix</code> ; (2) an edgelist in the form of a two-column dataframe; (3) an <code>igraph</code> object.
s	numeric: Sparsification exponent, $0 < s < 1$; smaller values yield sparser graphs
class	string: the class of the returned backbone graph, one of <code>c("original", "matrix", "Matrix", "igraph", "edgelist")</code> . If "original", the backbone graph returned is of the same class as U.
narrative	boolean: TRUE if suggested text & citations should be displayed.

Value

An unweighted, undirected, unipartite graph of class `class`.

Examples

```
U <- igraph::sbm.game(60, matrix(c(.75,.25,.25,.25,.75,.25,.25,.25,.75),3,3), c(20,20,20))
plot(U) #A hairball
sparse <- sparsify.with.lspar(U, s = 0.6, narrative = TRUE)
plot(sparse) #Clearly visible communities
```

sparsify.with.meetmin *Extract Goldberg and Roth's (2003) MeetMin backbone*

Description

sparsify.with.meetmin is a wrapper for `sparsify()` that extracts the meetmin backbone described by Goldberg and Roth (2003). It is equivalent to `sparsify(escape = "meetmin", normalize = "none", filter = "threshold", umst = FALSE)`.

Usage

```
sparsify.with.meetmin(U, s, class = "original", narrative = FALSE)
```

Arguments

U	An unweighted unipartite graph, as: (1) an adjacency matrix in the form of a matrix or sparse <code>Matrix</code> ; (2) an edgelist in the form of a two-column dataframe; (3) an <code>igraph</code> object.
s	numeric: Sparsification threshold, $0 < s < 1$; larger values yield sparser graphs
class	string: the class of the returned backbone graph, one of <code>c("original", "matrix", "Matrix", "igraph", "edgelist")</code> . If "original", the backbone graph returned is of the same class as U.
narrative	boolean: TRUE if suggested text & citations should be displayed.

Value

plot(U) #A hairball
sparse <- sparsify.with.meetmin(U, s = 0.5, narrative = TRUE)
plot(sparse) #Clearly visible communities
```

 sparsify.with.quadrilateral

Extract Nocaj et al.'s (2015) Quadrilateral Simmelian backbone

Description

sparsify.with.quadrilateral is a wrapper for `sparsify()` that extracts the quadrilateral Simmelian backbone described by Nocaj et al. (2015). It is equivalent to `sparsify(escape = "quadrilateral embeddedness", normalize = "embeddedness", filter = "threshold", umst = TRUE)`.

Usage

```
sparsify.with.quadrilateral(U, s, class = "original", narrative = FALSE)
```

Arguments

U	An unweighted unipartite graph, as: (1) an adjacency matrix in the form of a matrix or sparse <code>Matrix</code> ; (2) an edgelist in the form of a two-column dataframe; (3) an <code>igraph</code> object.
s	numeric: Sparsification exponent, $0 < s < 1$; larger values yield sparser graphs
class	string: the class of the returned backbone graph, one of <code>c("original", "matrix", "Matrix", "igraph", "edgelist")</code> . If "original", the backbone graph returned is of the same class as U.
narrative	boolean: TRUE if suggested text & citations should be displayed.

Value

Examples

```
U <- igraph::sbm.game(60, matrix(c(.75,.25,.25,.25,.75,.25,.25,.25,.75),3,3), c(20,20,20))
plot(U) #A hairball
sparse <- sparsify.with.quadrilateral(U, s = 0.5, narrative = TRUE)
plot(sparse) #Clearly visible communities in a connected graph
```

 sparsify.with.simmelian

Extract Nick et al's (2013) Simmelian backbone

Description

sparsify.with.simmelian is a wrapper for `sparsify()` that extracts the simmelian backbone described by Nick et al. (2013). It is equivalent to `sparsify(escape = "triangles", normalize = "embeddedness", filter = "threshold", umst = FALSE)`.

Usage

```
sparsify.with.simmelian(U, s, class = "original", narrative = FALSE)
```

Arguments

U	An unweighted unipartite graph, as: (1) an adjacency matrix in the form of a matrix or sparse <code>Matrix</code> ; (2) an edgelist in the form of a two-column dataframe; (3) an <code>igraph</code> object.
s	numeric: Sparsification threshold, $0 < s < 1$; larger values yield sparser graphs
class	string: the class of the returned backbone graph, one of <code>c("original", "matrix", "Matrix", "igraph", "edgelist")</code> . If "original", the backbone graph returned is of the same class as U.
narrative	boolean: TRUE if suggested text & citations should be displayed.

Examples

```
U <- igraph::sbm.game(60, matrix(c(.75,.25,.25,.25,.75,.25,.25,.25,.75),3,3), c(20,20,20))
plot(U) #A hairball
sparse <- sparsify.with.simmelian(U, s = 0.5, narrative = TRUE)
plot(sparse) #Clearly visible communities
```

 sparsify.with.skeleton

Extract Karger's (1999) skeleton backbone

Description

sparsify.with.skeleton is a wrapper for `sparsify()` that extracts the skeleton backbone described by Karger (1999), which preserves a specified proportion of random edges. It is equivalent to `sparsify(escore = "random", normalize = "none", filter = "proportion", umst = FALSE)`.

Usage

```
sparsify.with.skeleton(U, s, class = "original", narrative = FALSE)
```

Arguments

U	An unweighted unipartite graph, as: (1) an adjacency matrix in the form of a matrix or sparse <code>Matrix</code> ; (2) an edgelist in the form of a two-column dataframe; (3) an <code>igraph</code> object.
s	numeric: Proportion of edges to retain, $0 < s < 1$; smaller values yield sparser graphs
class	string: the class of the returned backbone graph, one of <code>c("original", "matrix", "Matrix", "igraph", "edgelist")</code> . If "original", the backbone graph returned is of the same class as U.
narrative	boolean: TRUE if suggested text & citations should be displayed.

Value

An unweighted, undirected, unipartite graph of class `class`.
