# Package 'bamlss'

November 9, 2022

```
Version 1.1-9
Date 2022-11-09
Title Bayesian Additive Models for Location, Scale, and Shape (and
      Beyond)
Description Infrastructure for estimating probabilistic distributional regression mod-
      els in a Bayesian framework.
      The distribution parameters may capture location, scale, shape, etc. and every parameter may de-
      on complex additive terms (fixed, random, smooth, spatial, etc.) similar to a generalized addi-
      tive model.
      The conceptual and computational framework is introduced in Umlauf, Klein, Zeileis (2019)
      <doi:10.1080/10618600.2017.1407325> and the R package in Umlauf, Klein, Si-
      mon, Zeileis (2021)
      <doi:10.18637/jss.v100.i04>.
Depends R (>= 3.5.0), coda, colorspace, mgcv

bamlss-package

Bayesian Additive Models for Location Scale and Shape (and Beyond)

#### **Description**

The **bamlss** package is a general tool for complex Bayesian regression modeling with structured additive predictors based on Markov chain Monte Carlo simulation. The design of this package substantially focuses on maximum flexibility and easy integration of new code and/or standalone systems. The package makes heavy use of mgcv infrastructures to build up all necessary model matrices and information from which it is relatively easy for the user to construct estimation algorithms or interfaces to existing software packages. The package can also be seen as an harmonized framework for regression modeling since it does not restrict to any type of problem. The main function in this package is bamlss, which is a wrapper function that calls optimizer and/or sampling functions for fitting Bayesian additive models for location scale and shape (and beyond). These model fitting functions can be exchanged by the user. Moreover, the package contains numerous functions for creating post-estimation results like summary statistics and effect plots etc.

Austria States and Topography

## **Description**

These two data sets Austria and AustriaTopo provide the states of Austria as a SpatialPolygonsDataFrame and the topography of Austria as data frame.

```
data("Austria")
```

#### **Format**

The AustriaTopo data contains the following variables:

lon: Numeric, longitude coordinates.lat: Numeric, latitude coordinates.alt: Numeric, altitude.

bamlss

Fit Bayesian Additive Models for Location Scale and Shape (and Beyond)

## **Description**

This is the main model fitting function of the package. Function bamlss() is a wrapper function that parses the data and the model formula, or extended bamlss.formula, as well as the bamlss.family into a bamlss.frame. The bamlss.frame then holds all model matrices and information that is needed for setting up estimation engines. The model matrices are based on mgcv infrastructures, i.e., smooth terms are constructed using smooth.construct and smoothCon. Therefore, all mgcv model term constructors like s, te, t2 and ti can be used. Identifiability conditions are imposed using function gam.side.

After the bamlss.frame is set up function bamlss() applies optimizer and/or sampling functions. These functions can also be provided by the user. See the details below on how to create new engines to be used with function bamlss().

Finally, the estimated parameters and/or samples are used to create model output results like summary statistics or effect plots. The computation of results may also be controlled by the user.

```
bamlss(formula, family = "gaussian", data = NULL,
    start = NULL, knots = NULL, weights = NULL,
    subset = NULL, offset = NULL, na.action = na.omit,
    contrasts = NULL, reference = NULL, transform = NULL,
    optimizer = NULL, sampler = NULL, samplestats = NULL,
    results = NULL, cores = NULL, sleep = NULL,
    combine = TRUE, model = TRUE, x = TRUE,
    light = FALSE, ...)
```

#### **Arguments**

formula A formula or extended formula, i.e., the formula can be a list of formulas

where each list entry specifies the details of one parameter of the modeled response distribution, see bamlss.formula. For incorporating smooth terms, all model term constructors implemented in mgcv such as s, te and ti can be used,

amongst others.

family A bamlss. family object, specifying the details of the modeled distribution such

as the parameter names, the density function, link functions, etc. Can be a character without the "\_bamlss" extension of the bamlss.family name.

data A data. frame or list containing the model response variable(s) and covariates

specified in the formula. By default the variables are taken from environment(formula):

typically the environment from which bamlss is called.

start A named numeric vector containing starting values to be send to the optimizer

and/or sampler function. For a possible naming convention for the parameters

see function parameters, but this is not restrictive and engine specific.

knots An optional list containing user specified knots, see the documentation of func-

tion gam.

weights Prior weights on the data.

subset An optional vector specifying a subset of observations to be used in the fitting

process.

offset Can be used to supply model offsets for use in fitting.

na.action A function which indicates what should happen when the data contain NA's. The

default is set by the na. action setting of options, and is na. omit if set to

NULL.

contrasts An optional list. See the contrasts.arg of model.matrix.default.

reference A character specifying a reference category, e.g., when fitting a multinomial

model.

transform A transformer function that is applied on the bamlss.frame. See, e.g., function

randomize and bamlss.engine.setup.

optimizer An optimizer function that returns, e.g., posterior mode estimates of the param-

eters as a named numeric vector. The default optimizer function is opt\_bfit. If

set to FALSE, no optimizer function will be used.

sampler A sampler function that returns a matrix of samples, the columns represent

the parameters, the rows the iterations. The returned matrix must be coerced to an object of class "mcmc", see as.mcmc. The default sampler function is

sam\_GMCMC. If set to FALSE, no sampler function will be used.

samplestats A function computing statistics from samples, per default function samplestats

is used. If set to FALSE, no samplestats function will be used. Note that this option is crucial for very large datasets, as computing statistics from samples

this way may be very time consuming!

results A function computing results from the parameters and/or samples, e.g., for cre-

ating effect plots, see function link{results.bamlss.default}. If set FALSE

no results function will be used.

cores	An integer specifying the number of cores that should be used for the sampler function. This is based on function mclapply of the <b>parallel</b> package.
sleep	Time the system should sleep before the next core is started.
combine	If samples are computed on multiple cores, should the samples be combined into one mcmc matrix?
model	If set to FALSE the model frame used for modeling is not part of the return value.
x	If set to FALSE the model matrices are not part of the return value.
light	Should the returned object be lighter, i.e., if light = TRUE the returned object will not contain the model.frame and design and penalty matrices are deleted.
	Arguments passed to the transformer, optimizer, sampler, results and samplestats function.

#### **Details**

The main idea of this function is to provide infrastructures that make it relatively easy to create estimation engines for new problems, or write interfaces to existing software packages.

The steps that are performed within the function are:

- First, the function parses the data, the formula or the extended bamlss.formula as well as the bamlss.family into a model frame like object, the bamlss.frame. This object holds all necessary model matrices and information that is needed for subsequent model fitting engines. Per default, all package mgcv smooth term constructor functions like s, te, t2 and ti can be used (see also function smooth.construct), however, even special user defined constructors can be included, see the manual of bamlss.frame.
- In a second step, the bamlss.frame can be transformed, e.g., if a mixed model representation of smooth terms is needed, see function randomize.
- Then an optimizer function is started, e.g., a function that finds posterior mode estimates of the parameters. A convention for model fitting engines is that such functions should have the following arguments:

```
optimizer(x, y, family, start, weights, offset, ...)

Internally, function bamlss() will send the x object that holds all model matrices, the response y object, the family object, starting values for the parameters, possible weights and offsets of the created bamlss. frame to the optimizer function (see the manual of bamlss. frame for more details on the x, y and other objects). The job of the optimizer is to return a named numeric vector of optimum parameters. The names of the parameters should be such that they can be uniquely mapped to the corresponding model matrices in x. See function parameters for more details on parameter names. The default optimizer function is bfit. The optimizer can return more information than only the optimum parameters. It is possible to return a list, the convention here is that an element named "parameters" then holds the named vector of estimated parameters. Possible other return values could be fitted values, the Hessian matrix, information criteria or information about convergence of the algorithm, etc. Note that the parameters are simply added to the bamlss. frame in an (list) entry named parameters.
```

• After the optimization step, a sampler function is started. The arguments of such sampler functions are the same as for the optimizer functions sampler(x, y, family, start, weights, offset, ...)

Sampler functions must return a matrix of samples, each row represents one iteration and the matrix can be coerced to mcmc objects. The function may return a list of samples, e.g., if multiple chains are returned each list entry then holds one sample matrix of one chain. The column names of the sample matrix should be the same as the names of estimated parameters. For a possible naming convention see function parameters, which ensures unique mapping of samples with the model matrices in the x object of the bamlss.frame. The samples are added to the bamlss.frame in an (list) entry named samples.

- Next, the samplestats function is applied. This function can compute any quantity from the samples and the x object, the arguments of such functions are samplestats(samples, x, y, family, ...) where argument samples are the samples returned from the sampler function, and x, y and family are the same objects as passed to the optimizer and or sampler functions. For example, the default function in bamlss() for this task is also called samplestats and returns the mean of the log-likelihood and the log-posterior computed of all samples, as well as the DIC.
- The last step is to compute more complex information about the model using the results function. The arguments of such results functions are results(bamlss.frame, ...) here, the full bamlss.frame including possible parameters and samples is passed to the function within bamlss(). The default function for this task is results.bamlss.default which returns an object of class "bamlss.results" for which generic plotting functions are

and a summary function is provided. Hence, the user can control the output of the model, the

Note that function transform(), optimizer(), sampler(), samplestats() and results() can be provided from the bamlss.family object, e.g., if a bamlss.family object has an element named "optimizer", which represents a valid optimizer function such as bfit, exactly this optimizer function will be used as a default when using the family.

#### Value

An object of class "bamlss". The object is in principle only a slight extension of a bamlss. frame, i.e., if an optimizer is applied it will hold the estimated parameters in an additional element named "parameters". If a sampler function is applied it will additionally hold the samples in an element named "samples". The same mechanism is used for results function.

If the optimizer function computes additional output next to the parameters, this will be saved in an element named "model.stats". If a samplestats function is applied, the output will also be saved in the "model.stats" element.

Additionally, all functions that are called are saved as attribute "functions" in the returned object.

## **Examples**

```
## Not run: ## Simulated data example.
d <- GAMart()</pre>
f <- num \sim s(x1) + s(x2) + s(x3) + te(lon, lat)
b <- bamlss(f, data = d)</pre>
summary(b)
plot(b)
plot(b, which = 3:4)
plot(b, which = "samples")
## Use of optimizer and sampler functions:
## * first run optimizer,
b1 <- bamlss(f, data = d, optimizer = opt_bfit, sampler = FALSE)
print(b1)
summary(b1)
## * afterwards, start sampler with staring values,
b2 <- bamlss(f, data = d, start = coef(b1), optimizer = FALSE, sampler = sam_GMCMC)
print(b2)
summary(b2)
## Continue sampling.
b3 <- continue(b2, n.iter = 12000, burnin = 0, thin = 10)
plot(b3, which = "samples")
plot(b3, which = "max-acf")
plot(b3, which = "max-acf", burnin = 500, thin = 4)
## End(Not run)
```

bamlss.engine.helpers BAMLSS Engine Helper Functions

#### **Description**

These functions can be useful when setting up new model fitting engines that are based on the setup function bamlss.engine.setup. See the examples.

#### Usage

```
## Functions to extract parameter states.
get.par(x, what = NULL)
get.state(x, what = NULL)
set.par(x, replacement, what)
## Function for setting starting values.
set.starting.values(x, start)
```

## Arguments

x For function get.par() and set.par() argument x is a named numeric vector.

For function get.state() argument x is an object of the smooth.construct list that is processed by function bamlss.engine.setup, i.e., which has a "state" object. For function set.starting.values() argument x is the x list, as re-

turned from function bamlss.frame.

what The name of the parameter(s) that should be extracted or replaced.

replacement The value(s) that should be used for replacement.

start The named numeric vector of starting values. The name convention is based on

function parameters.

bf$x <- set.starting.values(bf$x, start = start)
get.state(bf$x$mu$smooth.construct[["s(x1)"]], "b")
get.state(bf$x$mu$smooth.construct[["s(x1)"]], "tau2")</pre>
```

bamlss.engine.setup

BAMLSS Engine Setup Function

## **Description**

This function takes the x object of a bamlss.frame and adds additional objects that are useful for model fitting engines. This is applied only for 'regular' terms, e.g., as created by s and te. For special model terms the corresponding smooth.construct method is in charge of this (see also the examples for function bfit).

## Usage

```
bamlss.engine.setup(x, update = "iwls", propose = "iwlsC_gp",
do.optim = NULL, df = NULL, parametric2smooth = TRUE, ...)
```

#### **Arguments**

X	The x list, as returned from function bamlss.frame, holding all model matrices and other information that is used for fitting the model.
update	Sets the updating function for model terms, see function bfit.
propose	Sets the propose function for model terms, see function GMCMC.
do.optim	Adds list element "do.optim" in the "state" element, see the details below.
df	The initial degrees of freedom that should be assigned to a smooth model term, based on the trace of the smoother matrix. Note that df can be a named numeric vector. If the names match the labels of the model terms, the corresponding df are used, e.g., $df = c("s(x1)" = 1, "s(x2)" = 2)$ sets different dfs for each term.

#### parametric2smooth

Should parametric model terms be transformed into an artificial smooth model term and be added to the "smooth.construct" object within the x list? This feature is handy, since algorithms can then cycle over the "smooth.construct" object, only.

... Currently not used.

12 bamlss.formula

#### **Details**

For each model term in the "smooth.construct" object of the x list (as returned from bamlss.frame), this function adds a named list called "state" with the following entries:

- "parameters": A numeric vector. Regression coefficients are named with "b", smooth variances are named with "tau2".
- "fitted.values": Given the "parameters", the actual fitted values of the model term.
- "edf": Given the smoothing variances, the actual equivalent degrees of freedom (edf) of the model term.
- "do.optim": Should an optimizer function try to find optimum smoothing variances?

The state will be changed in each iteration and can be passed outside an updating function.

Additionally, if missing in the xt argument of a model term (see, e.g., function s for xt) the function adds the corresponding log-prior and its first and second order derivatives w.r.t. regression coefficients in functions grad() and hess().

Also, objects named "lower" and "upper" are added to each model term. These indicate the lower and upper boundaries of the parameter space.

#### Value

A transformed x list, as returned from function bamlss. frame.

#### See Also

```
bamlss.frame, bfit, GMCMC, get.par, set.par, get.state
```

## **Examples**

```
\label{eq:continuous_series} \begin{split} & d <- \text{GAMart()} \\ & bf <- \text{bamlss.frame(num} \sim \text{s(x1)} + \text{s(x2)}, \text{ data = d, family = "gaussian")} \\ & \text{names(bf$x$mu$smooth.construct)} \\ & bf$x <- \text{bamlss.engine.setup(bf$x, df = c("s(x1)" = 1, "s(x2)" = 3))} \\ & \text{names(bf$x$mu$smooth.construct)} \\ & \text{names(bf$x$mu$smooth.construct[["s(x1)"]])} \\ & \text{names(bf$x$mu$smooth.construct[["s(x1)"]]$state)} \\ & \text{sapply(bf$x$mu$smooth.construct, function(x) {} \\ & \text{c(x$state$edf, get.state(x, "tau2"))} \\ \}) \end{split}
```

bamlss.formula

Formulae for BAMLSS

## Description

This function creates an extended BAMLSS formula. In combination with a bamlss.family object, each parameter of the response distribution is linked to a single formula. If no formula is supplied for a parameter, a simple intercept only model is created. Moreover, the function identifies hierarchical structures, see the examples. This function is useful for creating complex model.frames for (hierarchical) multi-parameter models and is used by function bamlss.frame.

bamlss.formula 13

#### Usage

```
bamlss.formula(formula, family = NULL, specials = NULL, env = NULL, ...)
```

## **Arguments**

A simple formula, or a list of simple formulae, or an extended Formula. For formula lists or extended Formulae, each single formula represents one model for the respective parameter as specified in the family object.

A bamlss.family object.

A character vector specifying special functions to be used within formulae, see terms.object.

The environment that should be assigned to the formula.

... Arguments passed to the family.

#### Value

A named list of class "bamlss.formula". Each list entry specifies a model, e.g., for one parameter of a provided bamlss.family object. Each entry (parameter model) then holds:

formula A simple formula.

fake.formula A formula with all function calls being dropped, e.g., the formula  $y \sim s(x1) + c$ 

s(x2) is represented in the fake. formula entry as  $y \sim x1 + x2$ . The fake. formula

is useful for creating model frames.

#### See Also

```

```
## Simple formula without family object.
f \leftarrow bamlss.formula(y \sim x1 + s(x2))
print(f)
print(str(f))
## Complex formula with list of formulae.
f <- list(
  y1 \sim x1 + s(x2),
  y2 \sim x3 + te(lon, lat),
  u \sim x4 + x1
)
f <- bamlss.formula(f)</pre>
print(f)
print(names(f))
## Same formula but using extended formulae
## of package Formula.
f <- y1|y2|u \sim x1 + s(x2)|x3 + te(lon, lat)|x4 + x1
```

14 bamlss.frame

```
f <- bamlss.formula(f)</pre>
print(f)
print(names(f))
## Using a bamlss family object, e.g., gaussian_bamlss().
## The family has two parameters, mu and sigma, for
## each parameter one formula is returned. If no
## formula is specified an intercept only model is
## generated for the respective parameter.
f \leftarrow bamlss.formula(y \sim x1 + s(x2), family = gaussian_bamlss)
## Note, same as:
f \leftarrow bamlss.formula(y \sim x1 + s(x2), family = "gaussian")
print(f)
## Specify model for parameter sigma, too
f <- list(
  y \sim x1 + s(x2),
  sigma \sim x2 + te(lon, lat)
f <- bamlss.formula(f, family = "gaussian")</pre>
print(f)
## With complex hierarchical structures,
## each parameter is another list of formulae,
## indicated by the h1, ..., hk, names.
f <- list(
  y \sim x1 + s(x2) + id1,
  sigma \sim x2 + te(lon, lat) + id2,
  id1 \sim s(x3) + x4 + s(id3),
  id3 \sim x5 + s(x5, x6),
  id2 \sim x7
)
f <- bamlss.formula(f, family = "gaussian")</pre>
print(f)
```

bamlss.frame

Create a Model Frame for BAMLSS

## Description

This function parses the data and the model formula, or extended bamlss.formula, as well as the bamlss.family into a bamlss.frame object. The bamlss.frame then holds all model matrices and information that is needed for setting up estimation engines.

```
bamlss.frame(formula, data = NULL, family = "gaussian",
  weights = NULL, subset = NULL, offset = NULL,
  na.action = na.omit, contrasts = NULL,
```

bamlss.frame 15

```
knots = NULL, specials = NULL, reference = NULL,
model.matrix = TRUE, smooth.construct = TRUE,
ytype = c("matrix", "vector", "integer"),
scale.x = FALSE, scale.d = FALSE, ...)
```

# Arguments

`	,	
	formula	A formula or extended formula, i.e., the formula can be a list of formulas where each list entry specifies the details of one parameter of the modeled response distribution, see bamlss.formula. For incorporating smooth terms, all model term constructors implemented in mgcv such as s, te and ti can be used, amongst others.
	data	A data.frame or list containing the model response variable(s) and covariates specified in the formula. By default the variables are taken from environment(formula): typically the environment from which bamlss is called.
	family	A bamlss.family object, specifying the details of the modeled distribution such as the parameter names, the density function, link functions, etc.
	weights	Prior weights on the data.
	subset	An optional vector specifying a subset of observations to be used in the fitting process.
	offset	Can be used to supply model offsets for use in fitting.
	na.action	A function which indicates what should happen when the data contain NA's. The default is set by the na.action setting of options, and is na.omit if set to NULL.
	contrasts	An optional list. See the contrasts.arg of model.matrix.default.
	knots	An optional list containing user specified knots, see the documentation of function gam.
	specials	Specify new special terms here to be used with the bamlss.formula, see also terms.object.
	reference	A character specifying a reference category, e.g., when fitting a multinomial model.
	model.matrix	Logical, should model matrices for linear parts be returned?
	smooth.construc	et
		Logical, should model matrices, e.g., as returned from smooth.construct and smoothCon be part of returned bamlss.frame?.
	ytype	For categorical responses, should the response be a vector or matrix. If ytype == "matrix" codebamlss.frame() uses function model.matrix to construct the response matrix from levels. If the response is a factor ytype == "integer" will create an integer response.
	scale.x	Logical, should the model matrices of the linear parts be scaled?
	scale.d	Logical, should the numeric variables in the model frame be scaled?
		Arguments passed to function smooth.construct.bamlss.frame.

16 bamlss.frame

#### **Details**

The function parses the data, the formula or the extended bamlss.formula as well as the bamlss.family into a model frame like object, the bamlss.frame. This object holds all necessary model matrices and information that is needed for model fitting engines. Per default, all package mgcv smooth term constructor functions like s, te, t2 and ti can be used (see also function smooth.construct), however, even special user defined constructors can be included, see the examples below.

Function bamlss.frame() uses function model.matrix.bamlss.frame to compute all design matrices for simple linear parts, all smooth terms are parsed with function smooth.construct.bamlss.frame.

It is also possible to create a "bamlss.frame" using hierarchical formulae, see the example below.

#### Value

An list of class "bamlss.frame" with the following elements:

The initial call. call model.frame The model.frame used to compute all design matrices. formula The bamlss.formula. The bamlss.family object. family The terms.bamlss object. terms A named list, the elements correspond to the parameters that are specified within Х the bamlss.family object. For each parameter the corresponding formula, a fake. formula only holding the covariate names, a terms object, a model.matrix for the linear part and a list smooth.construct holding all information for smooth terms as returned from function link{smooth.construct.bamlss.frame} is created. The response data. У

bboost

bboost bboost

# **Description**

Wrapper function for applying bootstrap estimation using gradient boosting.

# Usage

```
## Bootstrap boosting.
bboost(..., data, type = 1, cores = 1,
    n = 2, prob = 0.623, fmstop = NULL,
    trace = TRUE, drop = FALSE, replace = FALSE)

## Plotting function.
bboost_plot(object, col = NULL)

## Predict method.
## S3 method for class 'bboost'
predict(object, newdata, ..., cores = 1, pfun = NULL)
```

# Arguments

	Arguments passed to bamlss and predict.bamlss.
data	The data frame to be used for modeling.
type	Type of algorithm, type = 1 uses all observations and samples with replacement, type = 2 uses only a fraction specified in prob and samples with replacement.
cores	The number of cores to be used.
n	The number of bootstrap iterations.
prob	The fraction that should be used to fit the model in each bootstrap iteration.
fmstop	The function that should return the optimum stopping iteration. The function must have two arguments: (1) the model end (2) the data. The function must return a list with two named arguments: (1) "mstop" the optimum stopping iteration and (2) a vector of the objective criterion that should be evaluated by the hold out sample data during each bootstrap iteration. See the examples.
trace	Prints out the current state of the bootstrap algorithm.
drop	Should only the best set of parameters be saved?
replace	Sampling with replacement, or sampling ceiling(nobs $*$ prob) rows of the data for fitting the n models.
object	The "bboost" object used for prediction and plotting.
col	The color that should be used for plotting.
newdata	The data frame predictions should be made for.
pfun	The prediction function that should be used, for example predictn could be used, too. Note that this is experimental.

## Value

A list of bamlss objects.

## End(Not run)
```

coef.bamlss

Extract BAMLSS Coefficients

## **Description**

Methods to extract coefficients of fitted bamlss objects, either coefficients returned from optimizer functions, or samples from a sampler functions.

Method confint.bamlss() produces credible intervals or parameter samples using quantiles.

```
## S3 method for class 'bamlss'
coef(object, model = NULL, term = NULL,
   FUN = NULL, parameters = NULL,
   pterms = TRUE, sterms = TRUE,
   hyper.parameters = TRUE, list = FALSE,
   full.names = TRUE, rescale = FALSE, ...)

## S3 method for class 'bamlss'
confint(object, parm, level = 0.95,
   model = NULL, pterms = TRUE, sterms = FALSE,
   full.names = FALSE, hyper.parameters = FALSE, ...)
```

22 coef.bamlss

#### **Arguments**

object An object of class "bamlss" model Character or integer. For which model should coefficients be extracted? Character or integer. For which term should coefficients be extracted? term FUN A function that is applied on the parameter samples. If is set to TRUE, additionally adds estimated parameters returned from an optiparameters mizer function (if available). Should coefficients of parametric terms be included? pterms Should coefficients of smooths terms be included? sterms hyper.parameters For smooth terms, should hyper parameters such as smoothing variances be included? list Should the returned object have a list structure for each distribution parameter? full.names Should full names be assigned, indicating whether a term is parametric "p" or smooth "s". rescale Should parameters of the linear parts be rescaled if the scale.d argument in bamlss.frame is set to TRUE. parm Character or integer. For which term should coefficients intervals be extracted? The credible level which defines the lower and upper quantiles that should be level

computed from the samples.

.. Arguments to be passed to FUN and function samples.

#### Value

Depending on argument list and the number of distributional parameters, either a list or vector/matrix of model coefficients.

#### See Also

bamlss.

colorlegend

Plot a Color Legend

#### **Description**

Function to generate a color legend, the legend may be added to an existing plot or drawn in a separate plotting window.

```
colorlegend(color = NULL, ncol = NULL, x = NULL, breaks = NULL,
  pos = "center", shift = 0.02, side.legend = 1L, side.ticks = 1L,
  range = NULL, lrange = NULL, width = 0.25, height = 0.05,
  scale = TRUE, xlim = NULL, ylim = NULL, plot = NULL, full = FALSE,
  add = FALSE, col.border = "black", lty.border = 1L, lwd.border = 1L,
  ticks = TRUE, at = NULL, col.ticks = "black", lwd.ticks = 1L,
  lty.ticks = 1L, length.ticks = 0.3, labels = NULL,
  distance.labels = 0, col.labels = "black", cex.labels = 1L,
  digits = 2L, swap = FALSE, symmetric = TRUE, xpd = NULL,
  title = NULL, side.title = 2, shift.title = c(0, 0),
  cex.title = 1, ...)
```

# Arguments

color	Character, integer. The colors for the legend, may also be a function, e.g colors = heat.colors.	
ncol	Integer, the number of different colors that should be generated if color is a function.	l
x	Numeric, values for which the color legend should be drawn.	
breaks	Numeric, a set of breakpoints for the colors: must give one more breakpoin than ncol.	ţ
pos	Character, numeric. The position of the legend. Either a numeric vector, e.g. pose = $c(0.1, 0.2)$ will add the legend at the $10\%$ point in the x-direction and at the $20\%$ point in the y-direction of the plotting window, may also be negative, or one of the following: "bottomleft", "topleft", "topright", "bottomright" "left", "right", "top", "bottom" and "center".	2
shift	Numeric, if argument pos is a character, shift determines the distance of the legend from the plotting box.	;
side.legend	Integer, if set to 2 the legend will be flipped by 90 degrees.	
side.ticks	Integer, if set to 2, the ticks and labels will be on the opposite site of the legend	
range	Numeric, specifies a range for x values for which the legend should be drawn.	
lrange	Numeric, specifies the range of legend.	
width	Numeric, the width of the legend, if scale = TRUE the width is proportional to the x-limits of the plotting window.	)
height	Numeric, the height of the legend, if scale = TRUE the height is proportional to the y-limits of the plotting window.	)
scale	Logical, if set to TRUE, the width and height of the legend will be calculated proportional to the x- and y-limits of the plotting window.	l
xlim	Numeric, the x-limits of the plotting window the legend should be added for numeric vector, e.g., returned from function range.	,
ylim	Numeric, the y-limits of the plotting window the legend should be added for numeric vector, e.g., returned from function range.	,
plot	Logical, if set to TRUE, the legend will be drawn in a separate plotting window.	
full	Logical, if set to TRUE, the legend will be drawn using the full window range.	
add	Logical, if set to TRUE, the legend will be added to an existing plot.	
col.border	The color of the surrounding border line of the legend.	
lty.border	The line type of the surrounding border line of the legend.	
lwd.border	The line width of the surrounding border line of the legend.	
ticks	Logical, if set to TRUE, ticks will be added to the legend.	
at	Numeric, specifies at which locations ticks and labels should be added.	
col.ticks	The colors of the ticks.	
lwd.ticks	The line width of the ticks.	
lty.ticks	The line type of the ticks.	
<pre>lwd.border ticks at col.ticks</pre>	The line width of the surrounding border line of the legend.  Logical, if set to TRUE, ticks will be added to the legend.  Numeric, specifies at which locations ticks and labels should be added.  The colors of the ticks.	

length.ticks	Numeric, the length of the ticks as percentage of the height or width of the colorlegend.
labels	Character, specifies labels that should be added to the ticks.
distance.labels	3
	Numeric, the distance of the labels to the ticks, proportional to the length of the ticks.
col.labels	The colors of the labels.
cex.labels	Text size of the labels.
digits	Integer, the decimal places if labels are numerical.
swap	Logical, if set to TRUE colors will be represented in reverse order.
symmetric	Logical, if set to TRUE, a symmetric legend will be drawn corresponding to the $+-\max(abs(x))$ value.
xpd	Sets the xpd parameter in function par.
title	Character, a title for the legend.
side.title	Integer, 1 or 2. Specifies where the legend is placed, either on top if side.title = 1 or at the bottom if side.title = 2.
shift.title	Numeric vector of length 2. Specifies a possible shift of the title in either x- or y-direction.
cex.title	Text size for the title.
	Other graphical parameters to be passed to function text.

## Value

A named list with the colors generated, the breaks and the function map, which may be used for mapping of x values to the colors specified in argument colors, please see the examples below.

```
## Play with colorlegend.
colorlegend()
colorlegend(side.legend = 2)
colorlegend(side.legend = 2, side.ticks = 2)

continue

Continue Sampling

# Description

This function takes a bamlss object which was created using a sampler function and continues sampling from the last state of the MCMC chain.

## Usage

```
continue(object, cores = NULL, combine = TRUE,
    sleep = NULL, results = TRUE, ...)
```

# Arguments

object	A bamlss object which contains samples.
cores	An integer specifying the number of cores that should be used for the sampler function. This is based on function mclapply of the <b>parallel</b> package.
combine	Should the new samples be combined with the old samples into one mcmc matrix? Note that if combine = FALSE and the number of iterations differ from one sampling step to the other there will be an error since the start and end points in the samples mcmc objects are different!
sleep	Time the system should sleep before the next core is started.
results	If a results function was used to create the bamlss object, should the results function be applied using the new samples?
	Arguments passed to the sampler function.

# Value

A bamlss object.

#### **Examples**

```
## Not run: ## Simulate and run model with MCMC.
set.seed(123)
d <- GAMart()
b <- bamlss(num ~ s(x1) + s(x2) + s(x3) + te(lon,lat), data = d)

## Continue sampling.
a <- continue(b)

## Plot all samples.
## plot(a, which = "samples")

## End(Not run)</pre>
```

cox\_predict

Cox Model Prediction

#### **Description**

This function takes a fitted Cox model, i.e., a model estimated by opt\_Cox or sam\_Cox and computes predictions given a new data set or the original values. Survival probabilities are computed using numerical integration, therefore, computation may take some time. To avoid problems with computer memory, the prediction of survival probabilities can be split into chunks and computed parallel on different cores.

## Usage

```
cox_predict(object, newdata,
  type = c("link", "parameter", "probabilities"),
  FUN = function(x) { mean(x, na.rm = TRUE) },
  time = NULL, subdivisions = 100, cores = NULL,
  chunks = 1, verbose = FALSE, ...)
```

## **Arguments**

object A "bamlss" object as returned from function bamlss using the optimizer opt\_Cox

or sampler function sam\_Cox.

newdata A data frame or list containing the values of the model covariates at which pre-

dictions are required. If missing newdata is the model.frame of the provided

model.

type Specifies the type of predictions that should be computed.

FUN A function that should be applied on each row of the samples of the additive

predictor, parameter or probabilities. Per default the function computes means

of samples, however, other functions like quantile can be supplied.

time numeric, specifies the time for which survival probabilities should be computed

if type = "probabilities". Note that this overwrites survival times that are

supplied in argument newdata.

cox\_predict 29

subdivisions How many time points should be created for each individual.

Cores Specifies the number of cores that should be used for prediction. The problem is split into core chunks, each chunk is then processed by one core.

Chunks The number of chunks that should be processed sequentially on one core. This way memory problems can be avoided when computing survival times for large problems.

Verbose Print progress information.

Arguments passed to predict.bamlss.

#### Value

Depending on the type of function provided in argument FUN, a numeric vector or matrix.

Crazy

Crazy simulated data

## **Description**

This function creates simulated data based on a crazy function.

# Usage

```
Crazy(n = 1000)
```

# Arguments

n

The number of observations to be simulated.

## Value

A data frame with response y and covariate x.

#### See Also

GAMart

# **Examples**

```
d <- Crazy(1000)
head(d)
plot(d)</pre>
```

**CRPS** 

Continuous Rank Probability Score

# Description

The function computes the continuous rank probability score (CRPS). Note that the function uses numerical integration, for highly efficient computation please see the **scoringRules** package.

```
CRPS(object, newdata = NULL,
  interval = c(-Inf, Inf), FUN = mean,
  term = NULL, ...)
```

DIC 31

# Arguments

object An object returned from bamlss.

newdata Optional new data that should be used for calculation.

interval The interval that should be used for numerical integration

FUN Function to be applied on the CRPS scores.

term If required, specify the model terms that should be used within the predict.bamlss function.

Arguments passed to function FUN.

## **Examples**

```
## Not run: ## Simulate data.
d <- GAMart()

## Model only including covariate x1.
b1 <- bamlss(num ~ s(x1), data = d)

## Now, also including x2 and x2.
b2 <- bamlss(num ~ s(x1) + s(x2) + s(x3), data = d)

## Compare using the CRPS score.
CRPS(b1)
CRPS(b2)

## End(Not run)</pre>
```

DIC

Deviance Information Criterion

## **Description**

Generic function returning the deviance information criterion (DIC) of a fitted model object.

```
DIC(object, ...)
```

32 dl.bamlss

# Arguments

object A fitted model object for which there exists a DIC method.
... Optionally more fitted model objects.

## **Examples**

```
## Not run: d <- GAMart()
b1 <- bamlss(num ~ s(x1), data = d)
b2 <- bamlss(num ~ s(x1) + s(x2), data = d)
DIC(b1, b2)
## End(Not run)</pre>
```

dl.bamlss

Deep Learning BAMLSS

# Description

This function interfaces **keras** infrastructures for high-level neural networks. The function can be used as a standalone model fitting engine such as bamlss or as an on top model engine to capture special features in the data that could not be captures by other model fitting engines.

# Usage

```
## Deep learning bamlss.
dl.bamlss(object, optimizer = "adam",
   epochs = 30, batch_size = NULL,
   nlayers = 2, units = 100, activation = "sigmoid",
   l1 = NULL, l2 = NULL,
   verbose = TRUE, ...)

## Predict method.
## S3 method for class 'dl.bamlss'
predict(object, newdata,
   model = NULL, type = c("link", "parameter"),
   drop = TRUE, ...)
```

# **Arguments**

object	An object of class "bamlss" or a bamlss.formula.
optimizer	Character or call to optimizer functions to be used within fit. For character, options are: "adam" "sgd", "rmsprop", "adagrad", "adadelta", "adamax", "adam". The default is optimizer_rmsprop with learning rate set to 1e-04.
epochs	Number of times to iterate over the training data arrays, see fit.
batch_size	Number of samples per gradient update, see fit.
nlayers	Number of hidden layers.

dl.bamlss 33

units	Number of nodes per hidden layer, can be a vector.
activation	Activation functions used for the hidden layers, can be a vector.
11	Shrinkage parameter for L1 penalty.
12	Shrinkage parameter for L2 penalty.
verbose	Print information during runtime of the algorithm.
newdata	A list or data. frame that should be used for prediction.
mode1	Character or integer specifying for which distributional parameter predictions should be computed.
type	If type = "link" the predictor of the corresponding model is returned. If type = "parameter" predictions on the distributional parameter scale are returned.
drop	If predictions for only one model are returned, the list structure is dropped.
	For function dl.boost(), arguments passed to bamlss.frame.

#### **Details**

The default **keras** model is a sequential model with two hidden layers with "relu" activation function and 100 units in each layer. Between each layer is a dropout layer with 0.1 dropout rate.

#### Value

For function dl.bamlss() an object of class "dl.bamlss". Note that extractor functions fitted and residuals.bamlss can be applied. For function predict.dl.bamlss() a list or vector of predicted values.

## WARNINGS

The BAMLSS deep learning infrastructure is still experimental!

engines

Show Available Engines for a Family Object

# Description

The function shows available optimizer and sampling engines for a given family object.

## Usage

```
engines(family, ...)
```

# **Arguments**

family A family object or the name of the family.
... Further family objects or names.

```
engines(gaussian_bamlss, "gamma", cox_bamlss)
```

family.bamlss 35

family.bamlss

Distribution Families in bamlss

#### **Description**

Family objects in **bamlss** specify the information that is needed for using (different) model fitting engines, e.g., the parameter names and corresponding link functions, the density function, derivatives of the log-likelihood w.r.t. the predictors, and so forth. The optimizer or sampler functions that are called by <code>bamlss</code> must know how much information is needed to interpret the model since the family objects are simply passed through. Family objects are also used for computing post-modeling statistics, e.g., for residual diagnostics or random number generation. See the details and examples.

```

36 family.bamlss

```
## Extractor functions:
## S3 method for class 'bamlss'
family(object, ...)
## S3 method for class 'bamlss.frame'
family(object, ...)
```

#### **Arguments**

object	An object of class "bamlss" or "bamlss.frame", see function bamlss and bamlss.frame.
k	The dimension of the multivariate normal. Note, if $k = 1$ function gaussian_bamlss() is called.
ar.start	Logical vector of length equal to the number of rows of the full data set used for modeling. Must hold entries TRUE indicating the start of a time series of a section. If ar.start = NULL lagged residuals are computed by simple shifting. See also bam.
link	Possible link functions.
tau	The quantile the should be fitted.
eps	Constant to be used for the approximation of the absolute function.
f1, f2	A family of class "gamlss.family", see package gamlss.dist.
	Arguments passed to functions that are called within the family object.

#### Details

The following lists the minimum requirements on a **bamlss** family object to be used with bamlss and bamlss.frame:

- The family object must return a list of class "family.bamlss".
- The object must contain the family name as a character string.
- The object must contain the names of the parameters as a character string, as well as the corresponding link functions as character string.

For most optimizer and sampling functions at least the density function, including a log argument, should be provided. When using generic model fitting engines like opt\_bfit or sam\_GMCMC, as well as for computing post-modeling statistics with function samplestats, and others, it is assumed that the density function in a family object has the following arguments:

```
d(y, par, log = FALSE, ...)
```

where argument y is the response (possibly a matrix) and par is a named list holding the evaluated parameters of the distribution, e.g., using a normal distribution par has two elements, one for the mean par\$mu and one for the standard deviation par\$sigma. The dots argument is for passing special internally used objects, depending on the type of model this feature is usually not needed.

Similarly, for derivative based algorithms, e.g. using iteratively weighted least squares (IWLS, see function opt\_bfit, the family object holds derivative functions evaluating derivatives of the log-likelihood w.r.t. the predictors (or expectations of derivatives). For each parameter, these functions also hold the following arguments:

```
score(y, par, ...)
```

family.bamlss 37

for computing the first derivative of the log-likelihood w.r.t. a predictor and

```
hess(y, par, ...)
```

for computing the negative second derivatives. Within the family object these functions are organized in a named list, see the examples below.

In addition, for the cumulative distribution function (p(y, par, ...)), for the quantile function (q(y, par, ...)) or for creating random numbers (r(n, par, ...)) the same structure is assumed. See, e.g., the code of function gaussian.bamlss().

Some model fitting engines can initialize the distributional parameters which oftentimes leads to much faster convergence. The initialize functions are again organized within a named list, one entry for each parameter, similar to the score and hess functions, e.g., see the code of family object gaussian.bamlss.

Using function bamlss, residuals.bamlss and predict.bamlss the family objects may also specify the transform()er, optimizer(), sampler(), samplestats(), results(), residuals() and predict() function that should be used with this family. See for example the setup of cox\_bamlss.

For using specialized estimation engines like sam\_JAGS it is recommended to supply any extra arguments needed by those engines with an additional list entry within the family object, e.g., using gaussian\_bamlss() with sam\_JAGS the family objects holds special details in an element named "bugs".

The examples below illustrate this setup. See also the code of the **bamlss** family functions.

plot(b)
## End(Not run)
```

fatalities

Weekly Number of Fatalities in Austria

## **Description**

This data set includes weekly fatalities in Austria from 2000 to 46 weeks in 2020. The data is taken from the Eurostat data base.

# Usage

```
data("fatalities")
```

fitted.bamlss 39

## **Format**

The fatalities data contains the following variables:

**num:** Integer, the number of fatalities.

**year:** Integer, the corresponding year fatalities are recorded. **week:** Integer, the corresponding week fatalities are recorded..

### References

Eurostat Database (2020). *Population and social conditions, demography and migration, mortality, weekly deaths, deaths by week and NUTS 3 region, Austria* https://ec.europa.eu/eurostat/

### **Examples**

```
data("fatalities")
plot(num ~ week, data = fatalities)
```

fitted.bamlss

**BAMLSS Fitted Values** 

## **Description**

Function to compute fitted values for bamlss models. The function calls predict.bamlss to compute fitted values from samples.

## Usage

```
## $3 method for class 'bamlss'
fitted(object, model = NULL, term = NULL,
   type = c("link", "parameter"), samples = TRUE,
   FUN = c95, nsamps = NULL, ...)
```

#### **Arguments**

object	An object of class "bamlss"
model	Character or integer, specifies the model for which fitted values should be computed.
term	Character or integer, specifies the model terms for which fitted values are required. Note that if samples = TRUE, e.g., term = $c("s(x1)", "x2")$ will compute the combined fitted values $s(x1) + x2$ .
type	If type = "link" the predictor of the corresponding model is returned. If type = "parameter" fitted values on the distributional parameter scale are returned.
samples	Should fitted values be computed using samples of parameters or estimated parameters as returned from optimizer functions (e.g., function bfit returns "fitted.values"). The former results in a call to predict.bamlss, the latter simply extracts the "fitted.values" of the bamlss object and is not model term specific.

40 GAMart

FUN A function that should be applied on the samples of predictors or parameters,

depending on argument type.

nsamps If the fitted bamlss object contains samples of parameters, computing fitted val-

ues may take quite some time. Therefore, to get a first feeling it can be useful to compute fitted values only based on nsamps samples, i.e., nsamps specifies the

number of samples which are extracted on equidistant intervals.

... Arguments passed to function predict.bamlss.

#### Value

Depending on arguments model, FUN and the structure of the bamlss model, a list of fitted values or simple vectors or matrices of fitted values.

#### See Also

```
bamlss, predict.bamlss.
```

#### **Examples**

```
## Not run: ## Generate some data.
d <- GAMart()

## Model formula.
f <- list(
    num ~ s(x1) + s(x2) + s(x3) + te(lon,lat),
    sigma ~ s(x1) + s(x2) + s(x3) + te(lon,lat)
)

## Estimate model.
b <- bamlss(f, data = d)

## Fitted values returned from optimizer.
f1 <- fitted(b, model = "mu", samples = FALSE)

## Fitted values returned from sampler.
f2 <- fitted(b, model = "mu", samples = TRUE, FUN = mean)
plot(f1, f2)

## End(Not run)</pre>
```

GAMart

GAM Artificial Data Set

#### **Description**

This function creates artificial GAM-type data. frames. The function is mainly used for testing purposes.

gamlss\_distributions 41

#### Usage

```
GAMart(n = 500, sd = 0.1, seed = FALSE,
   ti = c("none", "vcm", "main", "both"))
```

#### **Arguments**

n The number of observations.

sd Standard deviation of the normal errors.

seed Sets the seed to 111.

ti For tensor product interaction term, the type of interaction.

#### **Examples**

```
d <- GAMart()
head(d)

## Not run: b <- bamlss(num ~ s(x1) + s(x2) + s(x3) + te(lon,lat), data = d)
plot(b)

## End(Not run)</pre>
```

### **Description**

The functions searches in the **gamlss.dist** namespace for available distributions. It returns a named list of faily functions which can be used with bamlss.

### Usage

```
gamlss_distributions(type = c("continuous", "discrete"))
```

## **Arguments**

type

Character specifying the type of distribution to be extracted.

#### See Also

bamlss

```
## Not run:
dists <- gamlss_distributions(type = "continuous")
print(dists)
## End(Not run)</pre>
```

gF

GEFCom2014

GEFCom2014 Electricity Load Data

### Description

This data set is a subset of the electricity load data of the GEFCom2014 challenge. The full data is published in the Appendix of Hong T. et al. (2016).

## Usage

```
data("GEFCom2014")
```

#### **Format**

The GEFCom2014 contains the following variables:

date The date of recording.

load The corresponding electricty load.

gF

Get a BAMLSS Family

## **Description**

Function to get a family.bamlss object to be used for fitting. The main purpose of this function is to ease the handling of extra arguments to the family object.

### Usage

```
gF(x, ...)
```

Golf 43

# Arguments

x The name of the family.bamlss without the ".bamlss" extension.

... Arguments passed to the family object.

#### Value

```
A family.bamlss object.
```

#### See Also

```
family.bamlss.
```

## **Examples**

```
f <- gF(gaussian)
print(f)</pre>
```

Golf

Prices of Used Cars Data

### **Description**

This dataset is taken from the Regression Book and is about prices of used VW Golf cars.

#### Usage

```
data("Golf")
```

#### **Format**

The Golf data contains the following variables:

**price:** Numeric, sale price in 1000 Euro. **age:** Numeric, age of the car in month.

kilometer: Numeric, kilometer reading in 1000 kilometers.

tia: Numeric, month until the next TIA appointment (German TUEV).

**abs:** Factor, does the car have abs?

sunroof: Factor, does the car have a sunroof?

# References

Fahrmeir, L., Kneib, T., Lang, S. and Marx, B. (2013). Regression - Models, Methods and Applications, Springer. https://www.uni-goettingen.de/de/551357.html.

```
data("Golf")
plot(price ~ age, data = Golf)
plot(price ~ kilometer, data = Golf)
```

homstart\_data

	homstart_data	HOMSTART Precipitation Data
--	---------------	-----------------------------

## **Description**

This function downloads and compiles the HOMSTART-project data set. The data is downloaded from the Zentralanstalt fuer Meteorologie und Geodynamik (ZAMG, http://www.zamg.ac.at) and funded by the Austrian Climate Research Programme (ACRP) and is free for research purposes.

### Usage

```
homstart_data(dir = NULL, load = TRUE, tdir = NULL)
```

## **Arguments**

dir The directory where the homstart.rda file should be stored.
---

load Should the homstart data be loaded?

tdir An optional temporary directory where all downloaded files are processed.

## Value

A data frame containing the following variables:

raw	The daily precipitation observations.
cens	Precipitation observations censored at 0.
bin	Factor with levels "yes" or "no" indicating precipitation.
cat	Factor with levels "none", "low", "medium" and "high" indicating the amount of precipitation.
trend	A numeric time trend
month	Month of of the observation.
year	Year of the observation.
day	Day of the year.
lon	The longitude coordinate of the corresponding meteorological station.
lat	The latitude coordinate of the corresponding meteorological station.
id	Factor, meteorological station identifier.
cos1, cos2, sin1, sin2	
	Transformed time trend for harmonic regression.
weekend	Factor, with levels "yes" and "no" indication if the observation was measured on a weekend.
elevation	Numeric, the elevation of the meteorological station.

  verbose = FALSE, ...)
## Survival plot.
jm_survplot(object, id = 1, dt = NULL, steps = 10,
 points = TRUE, rug = !points)
```

#### Arguments

x The x list, as returned from function bamlss.frame (and transformed by function jm\_transform()), holding all model matrices and other information that is

used for fitting the model.

y The model response, as returned from function bamlss.frame.

data A data. frame or list containing the model response variable(s) and covariates

specified in the formula in long format. By default the variables are taken from environment(formula): typically the environment from which bamlss

is called.

terms The corresponding terms.bamlss object needed for processing.

knots An optional list containing user specified knots, see the documentation of func-

tion gam.

formula The corresponding bamlss.formula.

family The bamlss. family object.

subdivisions How many time points should be created for each individual.

timedependent A character vector specifying the names of parameters in x that are time-dependent.

Time grid design matrices are only computed for these parameters.

timevar A character specifying the name of the survival time variable in the data set.

idvar Depending on the type of data set, this is the name of the variable specifying identifier of individuals. Numeric, a starting value for the intercept of the association parameter alpha. alpha Numeric, a starting value for the intercept of the mu parameter. mu Numeric, a starting value for the intercept of the sigma parameter. sigma Logical, indicating if sparse matrix structures are used for updating and samsparse pling of mu parameter model terms. nonlinear Logical, indicating if association is nonlinear in mu. See Details on the different model specifications. edf alt Logical, indicating if an alternative computation of estimated degrees of freedom for penalized model terms should be used. start\_mu Starting values for the computation of mu. For estimating associations which are nonlinear in mu, knot placement is based on these starting values which can improve stability. Number of knots for spline basis of association nonlinear in mu. Reducing this k mu number improves stability of the estimation. A named numeric vector containing possible starting values, the names are start based on function parameters. weights Currently not supported. offset Currently not supported. criterion Information criterion to be used, e.g., for smoothing variance selection. Options are the corrected AIC "AICc" (see Details), the "BIC" and "AIC". Defaults to "AICc"? maxit Vector containing the maximum number of iterations for the backfitting algorithm with maxit[1] defining the iterations for the full model and maxit[2] the iterations within each predictor. maxit[2] defaults to 1 if only one value is specified. nu Vector of step lengths for parameter updates of one Newton-Raphson update for each predictor of the joint model. update.nu Should the updating step length be optimized in each iteration of the backfitting algorithm? Uses nu as starting value if set to TRUE. The relative convergence tolerance of the backfitting algorithm. eps The relative convergence tolerance of the backfitting algorithm for predictor alalpha.eps pha. ic.eps The relative convergence tolerance of the information criterion used, e.g., for smoothing variance selection. nback For computing ic.eps, how many iterations back should be included when computing relative convergence tolerance of the information criterion. verbose Print information during runtime of the algorithm. digits Set the digits for printing when verbose = TRUE. the number of MCMC iterations. n.iter

burnin	the burn-in phase of the sampler, i.e., the number of starting samples that should be removed.
thin	the thinning parameter for MCMC simulation. E.g., thin = 10 means, that only every 10th sampled parameter will be stored.
step	How many times should algorithm runtime information be printed, divides n.iter.
object	A "bamlss" object processed with the JM optimizer function opt_JM() ans/or sampler function sam_JM() for which the survival plot should be created.
newdata	Dataset for which to create predictions. Not needed for conditional survival probabilities.
type	Character string indicating which type of predictions to compute. link returns estimates for all predictors with the respective link functions applied, "parameter" returns the estimates for all pedictors, "probabilities" returns the survival probabilities conditional on the survival up to the last longitudinal measurement, and "cumhaz" return the cumulative hazard up to the survival time or for a time window after the last longitudinal measurement. If type is set to "loglik", the log-likelihood of the joint model is returned.
id	Integer or character, that specifies the individual for which the plot should be created.
dt	The time window after the last observed measurement for which predictions should be computed. The default is $0.4 * max(obstime)$ and obstime are the individual's longitudinal measurement times.
steps	Integer, the number of steps for which to evaluate the conditional survival probability up to dt.
FUN	A function that should be applied on the samples of predictors or parameters, depending on argument type.
cores	Specifies the number of cores that should be used for prediction. Note that this functionality is based on the parallel package.
chunks	Should computations be split into chunks? Prediction is then processed sequentially.
points	Should longitudinal observations be added to the plot.
rug	Should longitudinal observed time points be added on the x-axis to the plot.
	Currently not used.

## **Details**

We refer to the papers of Koehler et al. (2017a, b) for details on the flexible additive joint model. In short, we model the hazard of subject i an event at time t as

$$h_i(t) = \exp[\eta_{\lambda i}(t) + \eta_{\gamma i} + \eta_{\alpha i}(\eta_{\mu i}(t), t)]$$

with predictor  $\eta_{\lambda}$  for all survival covariates that are time-varying or have a time-varying coefficient (including the log baseline hazard), predictor  $\eta_{\gamma}$  for baseline survival covariates, predictor  $\eta_{\alpha}$  representing the potentially time-varying or nonlinear association between the longitudinal marker  $\eta_{\mu}$  and the hazard. The longitudinal response  $y_{ij}$  at time points  $t_{ij}$  is modeled as

$$y_{ij} = \eta_{\mu i}(t_{ij}) + e_{ij}$$

with independent normal errors  $N(0, \exp[\eta_{\sigma i}(t_{ij})]^2)$ .

Each predictor  $\eta_{ki}$  is a structured additive predictor, i.e. a sum of functions of covariates  $\eta_{ki} = \sum_{m=1}^{M_k} f_{km}(\boldsymbol{x}_{ki})$ . Each of these functions can be modeled parametrically or using basis function evaluations from the smooth constructors in **mgcv** such as s, te and ti and can include smooth time-varying, random or spatial effects. For the Bayesian estimation of these effects we specify corresponding priors: For linear or parametric terms we use vague normal priors, smooth and random effect terms are regularized by placing generic multivariate normal priors on the coefficients and for anisotropic smooths, when multiple smoothing variance parameters are involved, more complex prior are in place (cf. Koehler et al., 2017a). We use inverse Gamma hyper-priors, i.e. IG(0.001, 0.001) to obtain an inverse Gamma full conditional for the variance parameters. We estimate the posterior mode by maximizing the log-posterior of the model using a Newton-Raphson procedure, the posterior mean is obtained via derivative-based Metropolis-Hastings sampling. We recommend to use posterior mode estimates for a quick model assessment. In order to draw correct inferences from the model, posterior mean estimates should be computed. We approximate integration in the survival part of the likelihood using trapezoidal rule. For posterior mode estimation.

A variety specifications of the association  $\eta_{\alpha i}(\eta_{\mu i}(t),t)$  are possible with an important distinction between associations which are nonlinear in  $\eta_{\mu}$  for nonlinear = TRUE (Koehler et al. 2017b) or linear where  $\eta_{\alpha i}(\eta_{\mu i}(t),t)=\eta_{\alpha i}(t)\eta_{\mu i}(t)$  for nonlinear = FALSE (Koehler et al. 2017a).

#### Note

The indicator nonlinear for associations with are linear or nonlinear in  $\eta_{\mu}$  was named interaction] in earlier versions stages of the development.

Lasso Smooth Constructor

la

## Description

Smooth constructors and optimizer for Lasso penalization with bamlss. The penalization is based on a Taylor series approximation of the Lasso penalty.

### Usage

```
## Smooth constructor function.
la(formula, type = c("single", "multiple"), ...)
## Single Lasso smoothing parameter optimizer.
opt_lasso(x, y, start = NULL, adaptive = TRUE, lower = 0.001, upper = 1000,
  nlambda = 100, lambda = NULL, multiple = FALSE, verbose = TRUE,
 digits = 4, flush = TRUE, nu = NULL, stop.nu = NULL,
 ridge = .Machine$double.eps^0.5, zeromodel = NULL, ...)
lasso(x, y, start = NULL, adaptive = TRUE, lower = 0.001, upper = 1000,
  nlambda = 100, lambda = NULL, multiple = FALSE, verbose = TRUE,
 digits = 4, flush = TRUE, nu = NULL, stop.nu = NULL,
 ridge = .Machine$double.eps^0.5, zeromodel = NULL, ...)
## Lasso transformation function to set
## adaptive weights from an unpenalized model.
lasso_transform(x, zeromodel, nobs = NULL, ...)
## Plotting function for opt_lasso() optimizer.
lasso_plot(x, which = c("criterion", "parameters"),
  spar = TRUE, model = NULL, name = NULL, mstop = NULL,
  retrans = FALSE, color = NULL, show.lambda = TRUE,
 labels = NULL, digits = 2, ...)
## Extract optimum stopping iteration for opt_lasso() optimizer.
## Based on the minimum of the information criterion.
lasso_stop(x)
## Extract retransformed Lasso coefficients.
lasso_coef(x, ...)
```

#### **Arguments**

formula A formula like  $\sim x1 + x2 + ... + xk$  of variables which should be penalized with

Lasso.

type Should one single penalty parameter be used or multiple parameters, one for

each covariate in formula.

*Ia* 53

x For function opt\_lasso() and lasso\_transform() the x list, as returned from function bamlss.frame, holding all model matrices and other information that is used for fitting the model. For the plotting function and lasso\_stop()/lasso\_coef() the corresponding bamlss object fitted with the opt\_lasso() optimizer.

y The model response, as returned from function bamlss.frame.

start A vector of starting values. Note, Lasso smoothing parameters will be dropped.

adaptive Should adaptive weights be used for fused Lasso terms?

lower Numeric. The minimum lambda value.

Numeric. The maximum lambda value.

nlambda Integer. The number of smoothing parameters for which coefficients should be

estimated, i.e., the vector of smoothing parameters is build up as a sequence

from lower to upper with length nlambda.

lambda Numeric. A sequence/vector of lambda parameters that should be used.

multiple Logical. Should the lambda grid be exapnded to search for multiple lambdas,

one for each distributional parameter.

verbose Print information during runtime of the algorithm.

digits Set the digits for printing when verbose = TRUE. If the optimum lambda value is

plotted, the number of decimal decimal places to be used within lasso\_plot().

flush use flush. console for displaying the current output in the console.

nu Numeric or logical. Defines the step length for parameter updating of a model

term, useful when the algorithm encounters convergence problems. If nu = TRUE the step length parameter is optimized for each model term in each iteration of

the backfitting algorithm.

stop.nu Integer. Should step length reduction be stopped after stop.nu iterations of the

Lasso algorithm?

ridge A ridge penalty parameter that should be used when finding adaptive weights,

i.e., parameters from an unpenalized model. The ridge penalty is used to stabi-

lize the estimation in complex models.

zeromodel A model containing the unpenalized parameters, e.g., for each la() terms one

can place a simple ridge penalty with la(x, ridge = TRUE, sp = 0.1). This way it is possible to find the unpenalized parameters that can be used as adaptive

weights for fusion penalties.

nobs Integer, number of observations of the data used for modeling. If not supplied

nobs is taken from the number of rows from the model term design matrices.

which Which of the two provided plots should be created, character or integer 1 and 2.

spar Should graphical parameters be set by the plotting function?

model Character selecting for which model the plot should be created.

name Character, the name of the coefficient group that should be plotted. Note that

the string provided in name will be removed from the labels on the 4th axis.

mstop Integer vector, defines the path length to be plotted.

retrans Logical, should coefficients be re-transformed before plotting?

54 la

color Colors or color function that creates colors for the group paths.

show. lambda Logical. Should the optimum value of the penalty parameter lambda be shown?

labels A character string of labels that should be used on the 4 axis.

Arguments passed to the subsequent smooth constructor function. lambda controls the starting value of the penalty parameter, const the constant that is added within the penalty approximation. Moreover, fuse = 1 enforces nominal fusion of categorical variables and fuse = 2 ordered fusion within la() Note that la() terms with and without fusion should not be mixed when using the opt\_lasso()

optimizer function. For the optimizer opt\_lasso() arguments passed to func-

tion bfit.

#### Value

For function la(), similar to function s a simple smooth specification object.

For function opt\_lasso() a list containing the following objects:

fitted.values A named list of the fitted values based on the last lasso iteration of the modeled

parameters of the selected distribution.

parameters A matrix, each row corresponds to the parameter values of one boosting itera-

tion.

lasso.stats A matrix containing information about the log-likelihood, log-posterior and the

information criterion for each lambda.

Linear Effects for BAMLSS

### **Description**

This smooth constructor implements simple linear effects. The columns of the design matrix are automatically scaled. The main advantage of this constructor is speed when used in the BAMLSS boosting algorithm boost. Optionally, a ridge penalty can be added, please see the example.

56 LondonFire

### Usage

```
## Linear smooth constructor.
lin(...)
## For mgcv.
## S3 method for class 'linear.smooth.spec'
smooth.construct(object, data, knots, ...)
```

#### **Arguments**

```
... For function lin() a formula of the type ~x1+x2+x3 that specifies the covariates that should be modeled.

object, data, knots

See smooth.construct.
```

#### Value

Function lin(), similar to function s a simple smooth specification object.

b <- bamlss(f, data = d)
summary(b)

## End(Not run)</pre>
```

LondonFire

London Fire Data

# Description

Provides the compiled dwelling fire data of London in 2015. The data is provided as a SpatialPointsDataFrame in object LondonFire. In addition the boundary and borough information is provided in objects LondonBoundaries and LondonBoroughs. Locations of all fire stations in London of 2015 are provided in object LondonFStations.

model.frame.bamlss 57

#### Usage

```
data("LondonFire")
```

#### **Format**

The LondonFire data contains the following variables:

arrivaltime: Numeric, the time after the emergency call until the first fire engine arrived.

daytime: Numeric, The time of day at which the emergency call was received.

**fsintens:** Numeric, the fire station intensity at the location of the fire scene. The intensity is measured using a kernel density estimate of the LondonFStations using the **spatstat** package.

model.frame.bamlss

BAMLSS Model Frame

#### Description

Extracts the model frame of a bamlss or bamlss. frame object.

# Usage

```
## S3 method for class 'bamlss'
model.frame(formula, ...)
## S3 method for class 'bamlss.frame'
model.frame(formula, ...)
```

58 model.frame.bamlss

```
## Internal helper function for creating
## the model frame.
bamlss.model.frame(formula, data, family = gaussian_bamlss(),
  weights = NULL, subset = NULL, offset = NULL,
  na.action = na.omit, specials = NULL, contrasts.arg = NULL,
  drop.unused.levels = TRUE, ...)
```

## **Arguments**

formula	An object of class "bamlss" or "bamlss.frame".
data	A data. frame or list containing the model response variable(s) and covariates specified in the formula. By default the variables are taken from environment(formula).
family	A bamlss.family object, see function bamlss.
weights	Prior weights on the data.
subset	An optional vector specifying a subset of observations to be used in the fitting process.
offset	Can be used to supply model offsets for use in fitting.
na.action	A function which indicates what should happen when the data contain NA's. The default is set by the na.action setting of options, and is na.omit if set to NULL.
specials	Special function in formulas, see terms.object.
contrasts.arg	An optional list. See the contrasts.arg of model.matrix.default.
drop.unused.levels	
	Should factors have unused levels dropped?
	Arguments to be passed to bamlss.model.frame() and others.

#### Value

The data.frame containing the variables used for modeling with function bamlss.

#### See Also

```
bamlss, bamlss.frame, model.matrix.bamlss.frame.
```

```
## Not run: ## Generate some data.

## Extract the model frame.
head(model.frame(b))

## End(Not run)</pre>
```

```
model.matrix.bamlss.frame
```

Construct/Extract BAMLSS Design Matrices

## Description

The function creates design (or model) matrices for BAMLSS, i.e., for each parameter of a bamlss. family object.

#### Usage

```
## S3 method for class 'bamlss.frame'
model.matrix(object, data = NULL, model = NULL,
    drop = TRUE, scale.x = FALSE, ...)

## S3 method for class 'bamlss.formula'
model.matrix(object, data = NULL, model = NULL,
    drop = TRUE, scale.x = FALSE, ...)

## S3 method for class 'bamlss.terms'
model.matrix(object, data = NULL, model = NULL,
    drop = TRUE, scale.x = FALSE, ...)
```

#### **Arguments**

object	A bamlss.frame, bamlss.formula or terms.bamlss object.
data	A data frame or list.
model	Character or integer, specifies the model for which design matrices should be returned.
drop	If model matrices for only one model are returned, the list structure is dropped.
scale.x	Logical, should the model matrices of the linear parts be scaled?
	Not used.

#### Value

Depending on the type of model a named list of model matrices or a single model matrix.

### See Also

```
model.matrix, bamlss.frame, bamlss.formula, terms.bamlss.
```

60 n

#### **Examples**

```
## Generate some data.
d <- GAMart()

## Model formula.
f <- list(
    num ~ x1 + x2 + id,
    sigma ~ x3 + fac + lon + lat
)

## Create a "bamlss.frame".
bf <- bamlss.frame(f, data = d)

## Get the model matrices.
X <- model.matrix(bf)
head(X$sigma)

## Same with "bamlss.formula".
X <- model.matrix(bamlss.formula(f), data = d)
head(X$sigma)</pre>
```

Neural Networks for BAMLSS

n

# Description

This smooth constructor implements single hidden layer neural networks.

# Usage

```
## The neural network smooth constructor.
n(..., k = 10, type = 2)

## Initialize weights.
n.weights(nodes, k, r = NULL, s = NULL,
    type = c("sigmoid", "gauss", "softplus", "cos", "sin"),
    x = NULL, ...)

## Second weights initializer, internally calls n.weights.
make_weights(object, data, dropout = 0.2)

## Boosted neural net predictions.
predictn(object, newdata, model = NULL,
    mstop = NULL, type = c("link", "parameter"))
```

neighbormatrix 61

# Arguments

٠		For function n() a formula of the type $\sim x1+x2+x3$ that specifies the covariates that should be modeled by the neural network. For function predictn(), arguments to be passed to predict.bamlss.
k		For function $n()$ , the number of hidden nodes of the network. Note that one can set an argument $split = TRUE$ to $split$ up the neural network into, e.g., $nsplit = 5$ parts with k nodes each. For function $n.weights()$ , argument k is the number of input variables of the network (number of covariates).
t	ype	Integer. Type 1 fits a complete network in each boosting iteration, type = 2 selects the best fitting node in each boosting iteration. for function n.weights(), the type of activation function that should be used. For function predictn(), the type of prediction that should be computed.
n	odes	Number of nodes for each layer, i.e., can also be a vector.
r	, s	Parameters controlling the shape of the activation functions.
X		A scaled covariate matrix, the data will be used to identify the range of the weights.
0	bject, data	See smooth.construct. For function predictn(), a boosted "bamlss" object.
d	ropout	The fraction of inner weights that should be set to zero.
n	ewdata	The data frame that should be used for prediction.
m	odel	For which parameter of the distribution predictions should be computed.
m	stop	The stopping iteration for which predictions should be computed. The default is to return a matrix of predictions, each column represents the prediction of one boosting iteration.

## Value

Function n(), similar to function s a simple smooth specification object.

neighbormatrix	Compute a Neighborhood Matrix from Spatial Polygons

# Description

The function takes a SpatialPolygonsDataFrame and computes the neighbor penalty matrix that can be used to fit a Markov random field, e.g., using the smooth constructor smooth.construct.mrf.smooth.spec.

62 neighbormatrix

#### Usage

```
## Compute the neighborhood matrix.
neighbormatrix(x, type = c("boundary", "dist", "delaunay", "knear"),
   k = 1, id = NULL, nb = FALSE, names = NULL, ...)
## Plot neighborhood structure.
plotneighbors(x, add = FALSE, ...)
```

# Arguments

X	An object of class "SpatialPolygons" or "SpatialPolygonsDataFrame".
type	Which type of neighborhood structure should be used, "boundary" uses poly2nb, "dist" uses function dnearneigh, "delaunay" uses function tri2nb and option "knear" applies function knn2nb.
k	For type = "knear", specifies number of nearest neighbors.
id	An identifier variable for which the penalty matrix should be computed.
nb	Should only the neighborhood object be returned.
names	Specifies the column where the regions names are provided in the data slot in the "SpatialPolygonsDataFrame"
add	Should the neighborhood structure be added to an existing plot?
	Arguments to be passed to function poly2nb, dnearneigh, tri2nb or knn2nb.

# See Also

```

```

```
## Not run: data("LondonFire")

## Compute polygon boundary based
## neighborhood matrix.
nm <- neighbormatrix(LondonBoroughs)
print(nm)

## Plot neighborhood structures.
plotneighbors(LondonBoroughs)
plotneighbors(LondonBoroughs, type = "delaunay")
plotneighbors(LondonBoroughs, type = "dist", d1 = 0, d2 = 0.15)
## End(Not run)</pre>
```

opt_bbfit	Batchwise Backfitting	

# Description

Batchwise backfitting estimation engine for GAMLSS using very large data sets.

## Usage

```
## Batchwise backfitting engine.
opt_bbfit(x, y, family, shuffle = TRUE, start = NULL, offset = NULL,
    epochs = 1, nbatch = 10, verbose = TRUE, ...)

bbfit(x, y, family, shuffle = TRUE, start = NULL, offset = NULL,
    epochs = 1, nbatch = 10, verbose = TRUE, ...)

## Parallel version.
opt_bbfitp(x, y, family, mc.cores = 1, ...)

## Loglik contribution plot.
contribplot(x, ...)
```

#### **Arguments**

х	For function bfit() the x list, as returned from function bamlss.frame, holding all model matrices and other information that is used for fitting the model. For the updating functions an object as returned from function smooth.construct or smoothCon. For function contribplot(), a "bamlss" object using bbfit() with argument select = TRUE.
У	The model response, as returned from function bamlss.frame.
family	A <b>bamlss</b> family object, see family.bamlss.
shuffle	Should observations be shuffled?
start	A named numeric vector containing possible starting values, the names are based on function parameters.
offset	Can be used to supply model offsets for use in fitting, returned from function bamlss.frame.
epochs	For how many epochs should the algorithm run?
nbatch	Number of batches. Can also be a number between 0 and 1, i.e., determining the fraction of observations that should be used for fitting.
verbose	Print information during runtime of the algorithm.
mc.cores	On how many cores should estimation be started?
	For bbfitp() all arguments to be passed to bbfit().

#### **Details**

The algorithm uses batch-wise estimation of regression coefficients and smoothing variances. The smoothing variances are estimated on an hold-out batch. This way, models for very large data sets can be estimated. Note, the algorithm can work in combination with the **ff** and **ffbase** package, i.e., the entire data is never in the computer RAM. Therefore, the data can either to be stored as comma separated file on disc or provided as "ffdf" data frame, see also the examples.

The optimizer functions use additional arguments:

- batch\_ids. This argument can either be a list of indices specifying the batches that should be used for estimation, or a vector of length 2, where the first element specifies the number of observations that should be sampled for each batch and the second argument specifies the number of batches, see the example.
- nu, the step length control parameter. Defaults to nu = 0.05. If argument slice = TRUE then nu = 1.
- loglik, defaults to loglik = FALSE. If set to loglik = TRUE the "out-of-sample" log-likelihood is used for smoothing variance estimation.
- aic, defaults to aic = FALSE, If set to aic = TRUE the "out-of-sample" AIC is used for smoothing variance estimation.
- eps\_loglik, defaults to eps\_loglik = 0.01. This argument specifies the relative change in the "out-of-sample" log-likelihood that is needed such that a model term gets updated.
- select, defaults to select = FALSE. If set to select = TRUE, the algorithm only selects the model term with the largest contribution in the "out-of-sample" log-likelihood for updating in each iteration/batch.
- always, defaults to always = FALSE. If set to always = TRUE no log-likelihood contribution checks will be used and model terms are always updated.
- K, defaults to K = 2. This argument controls the penalty on the degrees of freedom in the computation of the AIC.
- slice, defaults to slice = FALSE. If set to slice = TRUE, slice sampling using the "out-of-sample" log-likelihood or AIC is used for smoothing variance estimation. Moreover, always = TRUE, eps\_loglik = -Inf and nu = 1. If slice is an integer n, slice sampling is started after n iterations, before smoothing variances are optimized.

When using function opt\_bbfitp, the parameter updates are stored as "mcmc" objects. In this case the traceplots can be visualized using plot.bamlss.

#### Value

For function opt\_bbfit() a list containing the following objects:

fitted.values A named list of the fitted values of the modeled parameters of the selected dis-

tribution.

parameters The estimated set regression coefficients and smoothing variances.

shuffle Logical

runtime The runtime of the algorithm.

## Not run: ## Simulate data.
set.seed(123)
d \leftarrow GAMart(n = 27000, sd = -1)
## Write data to disc.
tf <- tempdir()</pre>
write.table(d, file.path(tf, "d.raw"), quote = FALSE, row.names = FALSE, sep = ",")
## Model formula.
f <- list(
  y \sim s(x1,k=40) + s(x2,k=40) + s(x3,k=40) + te(lon,lat,k=10),
  sigma \sim s(x1,k=40) + s(x2,k=40) + s(x3,k=40) + te(lon,lat,k=10)
## Specify 50 batches with 1000 observations.
batch_ids <- c("nobs" = 1000, "nbatch" = 50)
## Note, can also be a list of indices, e.g.
## batch_ids <- lapply(1:50, function(i) { sample(1:nrow(d), size = 1000) })</pre>
## Different flavors:
## (1) Using "out-of-sample" aic for smoothing
       variance estimation. Update is only accepted
       if the "out-of-sample" log-likelihood is
##
##
       increased. If data is a filepath, the data set is
##
       read into R using package ff and model and
       design matrices are processed with ff. This may
##
##
       take some time depending on the size of the data.
set.seed(1)
b1 <- bamlss(f, data = file.path(tf, "d.raw"),
  sampler = FALSE, optimizer = opt_bbfit,
  batch_ids = batch_ids, nu = 0.1, aic = TRUE, eps_loglik = -Inf,
  always = FALSE)
## Plot estimated effects.
## plot(b1)
## Plot coefficient paths for x3 in mu.
## pathplot(b1, name = "mu.s.s(x3).b")
## (2) Same but always update, this mimics the classic SGD.
       Note, for prediction only the last iteration is
##
       used in this case. To use more iterations use opt_bbfitp(),
##
       Then iterations are stored as "mcmc" object and we can
##
       predict using the burnin argment, e.g.,
       p <- predict(b2, model = "mu", burnin = 35)</pre>
set.seed(2)
```

```
b2 <- bamlss(f, data = file.path(tf, "d.raw"),
  sampler = FALSE, optimizer = opt_bbfit,
  batch_ids = batch_ids, nu = 0.1, aic = TRUE, eps_loglik = -Inf,
  always = TRUE)
## Plot coefficient paths for x3 in mu.
## pathplot(b2, name = "mu.s.s(x3).b")
## (3) Boosting type flavor, only update model term with
       the largest contribution in the "out-of-sample"
##
       log-likelihood. In this case, if edf = 0 during
##
##
       runtime of the algorithm, no model has an additional
##
       contribution and the algorithm converges. This
       behavior is controlled by argument eps_loglik, the
       higher eps_loglik, the more restrictive is the
##
       updating step.
## Initialize intercepts.
set.seed(0)
b0 <- bamlss(num ~ 1, data = d, sampler = FALSE, optimizer = opt_bbfitp,
  batch_ids = batch_ids, slice = TRUE)
## Compute starting values, remove the first
## 10 iterates and compute the mean of the
## remaining iterates.
start <- coef(b0, FUN = mean, burnin = 10)</pre>
## Start boosting, only update if change in
## "out-of-sample" log-likelihood is 0.1
## eps_loglik = 0.001.
set.seed(3)
b3 <- bamlss(f, data = d, sampler = FALSE, optimizer = opt_bbfit,
    batch_ids = batch_ids, nu = 0.1, aic = TRUE, eps_loglik = 0.001,
    select = TRUE, always = FALSE, start = start)
## Plot log-likelihood contributions.
## contribplot(b3)
## In this case, the algorithm did not converge,
## we need more iterations/batches.
## Note, prediction uses last iterate.
p3 <- predict(b3, model = "mu")
## (4) Use slice sampling under the "out-of-sample"
##
       log likelihood for estimation of smoothing
##
       variances. In this case model terms are always
       updated ad parameter paths behave like a MCMC
##
       chain. Therefore, use opt_bbfitp(), which stores
##
       parameter paths as "mcmc" objects and we can
##
       inspect using traceplots. Note nu = 1 if
       slice = TRUE.
##
set.seed(4)
b4 <- bamlss(f, data = d, sampler = FALSE, optimizer = opt_bbfitp,
```

```
batch_ids = batch_ids, aic = TRUE, slice = TRUE)

## plot(b4)

## Plot parameter updates/samples.

## plot(b4, which = "samples")

## Predict with burnin and compute mean

## prediction of the last 20 iterates.

p4 <- predict(b4, model = "mu", burnin = 30, FUN = mean)

## End(Not run)</pre>
```

opt\_bfit

Fit BAMLSS with Backfitting

### **Description**

This optimizer function is a generic tool for fitting BAMLSS using a backfitting algorithm. The backfitting procedure is based on iteratively weighted least squares (IWLS) for finding posterior mode estimates, however, the updating methods for model terms can be more general, see the details section. In addition, the default IWLS updating scheme implements optimum smoothing variance selection based on information criteria using a stepwise approach.

#### Usage

```
## Optimizer functions:
opt_bfit(x, y, family, start = NULL, weights = NULL, offset = NULL,
  update = "iwls", criterion = c("AICc", "BIC", "AIC"),
  eps = .Machine$double.eps^0.25, maxit = 400,
 outer = NULL, inner = FALSE, mgcv = FALSE,
 verbose = TRUE, digits = 4, flush = TRUE,
 nu = TRUE, stop.nu = NULL, ...)
bfit(x, y, family, start = NULL, weights = NULL, offset = NULL,
  update = "iwls", criterion = c("AICc", "BIC", "AIC"),
  eps = .Machine$double.eps^0.25, maxit = 400,
 outer = NULL, inner = FALSE, mgcv = FALSE,
 verbose = TRUE, digits = 4, flush = TRUE,
 nu = TRUE, stop.nu = NULL, ...)
## Model term updating functions:
bfit_iwls(x, family, y, eta, id, weights, criterion, ...)
bfit_iwls_Matrix(x, family, y, eta, id, weights, criterion, ...)
bfit_lm(x, family, y, eta, id, weights, criterion, ...)
bfit_optim(x, family, y, eta, id, weights, criterion, ...)
bfit_glmnet(x, family, y, eta, id, weights, criterion, ...)
```

#### **Arguments**

x For function opt\_bfit() the x list, as returned from function bamlss.frame,

holding all model matrices and other information that is used for fitting the model. For the updating functions an object as returned from function smooth.construct

or smoothCon.

y The model response, as returned from function bamlss.frame.

family A bamlss family object, see family.bamlss.

start A named numeric vector containing possible starting values, the names are

based on function parameters.

weights Prior weights on the data, as returned from function bamlss.frame.

offset Can be used to supply model offsets for use in fitting, returned from function

bamlss.frame.

update Sets the updating function for model terms, e.g. for a term s(x) in the model for-

mula. Per default this is set to "iwls", a character pointing to the set of updating functions, see above. Other options are "optim" and "lm" etc., however, this is more experimental and should not be set by the user. Another option is to pass a full updating function which should be used for each model term, the structure of updating functions is described in the details below. Model terms may also have different updating functions, see the example section implementing a new

model term constructor for Gompertz growth curves using this feature.

criterion Set the information criterion that should be used, e.g., for smoothing variance

selection. Options are the corrected AIC "AICc", the "BIC" and "AIC".

eps The relative convergence tolerance of the backfitting algorithm.

maxit The maximum number of iterations for the backfitting algorithm

outer Should the current working observations and weights be computed in one outer

iteration, otherwise the working observations are computed anew for each model term updating step. The default will run one outer iteration first, afterwards

model weights are computed for each term anew.

inner Should the model terms for one parameter of the modeled distribution be fully

updated until convergence in an inner iteration, i.e., the algorithm waits until coefficients for the current distribution parameter do not change anymore before updating the part parameter.

updating the next parameter.

mgcv Should the **mgcv** gam function be used for computing updates in an inner iter-

ation with working observations provided in an outer iteration.

verbose Print information during runtime of the algorithm. digits Set the digits for printing when verbose = TRUE.

flush use flush.console for displaying the current output in the console.

nu Logical, numeric or NULL. Function opt\_bfit() uses step length optimization

of parameters when updating a model term, useful to encounter convergence problems of the algorithm. If nu = TRUE the step length parameter is optimized for each model term in each iteration of the backfitting algorithm. If nu is numeric, e.g. nu = 1, then nu is halfed until an improvement in the log-posterior is obtained or nu is smaller than .Machine\$double.eps. If nu = NULL, no step length optimization is performed. Note, using very large data sets it is usually

better to switch of step length optimization.

Integer. Should step length reduction be stopped after stop. nu iterations of the stop.nu backfitting algorithm? eta The current value of the predictors, provided as a named list, one list entry for each parameter. The names correspond to the parameter names in the family object, see family bamlss. E.g., when using the gaussian\_bamlss family object, the current values for the mean can be extracted by eta\\$mu and for the standard deviation by eta\\$sigma. id Character, the name of the current parameter for which the model term should be updated. For function opt\_bfit(), arguments passed to function bamlss.engine.setup. For updating functions, within the dots argument the actual iteration number of the backfitting algorithm, the actual total number of equivalent degrees of freedom edf and vectors z and hess only if argument outer = TRUE are provided.

#### **Details**

This algorithm is based on iteratively weighted least squares (IWLS) for BAMLSS, i.e., a Newton-Raphson or Fisher scoring algorithm is applied, similar to Rigby~and~Stasinopoulos~(2005). The algorithm utilizes the chain rule for computing derivatives of the log-posterior w.r.t. regression coefficients, therefore, to compute the working observations and weights only the derivatives of the log-likelihood w.r.t. the predictors are required.

It is assumed that the provided family object holds functions for computing the first and second order derivatives of the log-likelihood w.r.t. the predictors. These Functions are provided within the named lists "score" and "hess" within the family object. See the documentation of family.bamlss and the code of the provided families, e.g. gaussian\_bamlss, for examples of the required structure.

The algorithm either updates each model term over all distributional parameters sequentially, or does a full update until convergence for model terms for one distributional parameter before updating the next parameter, see argument inner. Additionally, working observations and weights can be computed only once in an outer iteration.

Starting values of regression coefficients and smoothing variances can be supplied, moreover, if a family object holds functions for initializing the distributional parameters, see also family.bamlss, starting values are based on the initialize functions.

The default updating function for model terms is based on IWLS, which is assigned by function bamlss.engine.setup, however, special updating functions can be used. This is achieved by providing an updating function to argument update, which should be used for all model terms. Another option is to set the updating function within the xt argument of the **mgcv** smooth term constructor functions, see e.g. function s. If the xt list then holds an element named "update", which is a valid updating function, this updating function is used for the corresponding model term. This way it is possible to call different (special) updating functions for specific terms, e.g., that do not fit in the IWLS scheme. See the examples below. Note that this does not work if mgcv = TRUE, since the gam function assumes a strict linear representation of smooth terms.

A model term updating function has the following arguments:

```
update(x, family, y, eta, id, weights, criterion, ...)
```

Here x is an object as returned from function smooth.construct or smoothCon. The x object is preprocessed by function bamlss.engine.setup, i.e., an element called "state" is assigned. The state element represents the current state of the model term holding the current values of the parameters with corresponding fitted values, as well as equivalent degrees of freedom, see also the values that are returned by such functions below. The backfitting algorithm uses the state of a model term for generating updates of the parameters. Note that for special model terms the state list should already be provided within the call to the corresponding smooth constructor function, see the growth curve example below.

In addition, for special model terms the fitted values may not be computed by a linear combination of the design matrix and the coefficients. Therefore, the x object should hold an element named "fit.fun" which is a function for computing the fitted values. See also smooth.construct.bamlss.frame and predict.bamlss that use this setup. The arguments of fitting functions are

```
fit.fun(X, b, ...)
```

where X is the design matrix and b is the vector of coefficients. Hence, for usual IWLS updating the fitted values are computed by X \*\* b. For special terms like nonlinear growth curves this may not be the case, see the example below. The fitting functions are assigned by bamlss.engine.setup, unless the function is already provided after calling the constructor function smooth.construct or smoothCon. Note that the dots argument is usually not needed by the user.

The default updating function is bfit\_iwls(). Function bfit\_iwls\_Matrix() uses the sparse matrix infrastructures of package **Matrix**. The **Matrix** package and bfit\_iwls\_Matrix() is used for model terms where the maximum number of non-zero entries in the design matrix is less than half of the total number of columns, if an additional argument force.Matrix is set to TRUE in the opt\_bfit() call.

The IWLS updating functions find optimum smoothing variances according to an information criterion using a stepwise approach, i.e., in each iteration and for each model term update the updating functions try to find a better smoothing variance to control the trade-off between over-smoothing and nonlinear functional estimation. The search interval is centered around the current state of the smoothing variances, hence, in each iteration only a slight improvement is achieved. This algorithm is based on Belitz~and~Lang~(2008) and can also be viewed as a boosting approach for optimization.

### Value

For function opt\_bfit() a list containing the following objects:

fitted.values A named list of the fitted values of the modeled parameters of the selected dis-

tribution.

parameters The estimated set regression coefficients and smoothing variances.

edf The equivalent degrees of freedom used to fit the model.

logLik The value of the log-likelihood.

logPost The value of the log-posterior.

IC The value of the information criterion.

converged Logical, indicating convergence of the backfitting algorithm.

For updating functions a list providing the current state

fitted.values The resulting fitted values after updating.

parameters The resulting named numeric vector of updated model term parameters. Coeffi-

cients should be named with "b1",..., "bk", where k is the total number of coefficients. Smoothing variances should be named with "tau21",..., "tau2m", where m is the total number of smoothing variances assigned to the model term.

edf The equivalent degrees of freedom used to produce the fitted values.

hessian Optional, the coefficient Hessian information

log.prior Optional, the value of the log-prior of the model term.

plot(x, ...)
## Model frame for out-of-sample selection.
boost_frame(formula, train, test, family = "gaussian", ...)
```

### **Arguments**

X	For function opt_boost() the x list, as returned from function bamlss.frame, holding all model matrices and other information that is used for fitting the model. For the plotting function the corresponding bamlss object fitted with the opt_boost() optimizer.
у	The model response, as returned from function bamlss.frame.
family	A bamlss family object, see family.bamlss.
weights	Prior weights on the data, as returned from function bamlss.frame.
offset	Can be used to supply model offsets for use in fitting, returned from function

bamlss.frame.

nu Numeric, between [0, 1], controls the step size, i.e., the amount that should be

added to model term parameters.

nu. adapt Logical. If set to TRUE (default) step size nu is divided by 2, if current boosting

iteration did not improve the loglikelihood.

df Integer, defines the initial degrees of freedom that should be assigned to each

smooth model term. May also be a named vector, the names must match the

model term labels, e.g., as provided in summary.bamlss.

maxit Integer, the maximum number of boosting iterations.

mstop For convenience, overwrites maxit.

maxq Integer, defines the maximum number of selected base-learners. The algorithm

stops if this numer is exceeded.

qsel.splitfactor

Logical, if set to TRUE dummy variables of categorical predictors are counted

individually.

name Character, the name of the coefficient (group) that should be plotted. Note that

the string provided in name will be removed from the labels on the 4th axis.

drop Character, the name of the coefficient (group) that should not be plotted.

labels A character string of labels that should be used on the 4 axis.

Color Colors or color function that creates colors for the (group) paths.

verbose Print information during runtime of the algorithm.

digits Set the digits for printing when verbose = TRUE.

flush use flush. console for displaying the current output in the console.

eps The tolerance used as stopping mechanism, see argument nback.

nback Integer. If nback is not NULL, then the algorithm stops if the the change in the

log-likelihood of the last nback iterations is smaller or equal to eps. If maxit =

NULL the maximum number of iterations is set to 10000.

plot Should the boosting summary be printed and plotted?

initialize Logical, should intercepts be initialized?

stop.criterion Character, selects the information criterion that should be used to determine

the optimum number of boosting iterations. Either "AIC" or "BIC" is possible. Note that this feature requires to compute hat-matrices for each distributional parameter, therefore, the routine may be slow and computer storage intensive.

select.type Should model terms be selected by the log-likelihood contribution, select.type

= 1, or by the corresponding stop.criterion, select.type = 2.

force.stop Logical, should the algorithm stop if the information criterion increases?

do.optim Logical. Should smoothing parameters be optimized in each boosting iteration?

hatmatrix Logical, if set to TRUE the hat-matrices for each distributional parameter will

be computed. The hat-matrices are used to determine the effective (equivalent) degrees of freedom in each boosting iteration, i.e., it is possible to compute information criteria like the AIC or BIC for selecting the optimum number of

boosting iterations.

reverse.edf Logical. Instead of computing degrees of freedom with hat-matrices, the ac-

tual smoothing parameters are reverse engineered to compute the corresponding

actual smoother matrix. Note that this option is still experimental.

approx.edf Logical. Another experimental and fast approximation of the degrees of free-

dom.

always Logical or character. Should the intercepts forced to be updated in each boost-

ing iteration? If always = TRUE each intercept of each distributional parameter is updated, if always = "best" only the intercept corresponding to the distribu-

tional of the best fitting model term is updated.

object A bamlss object that was fitted using opt\_boost().

summary Should the summary be printed?

which Which of the three provided plots should be created?

intercept Should the coefficient paths of intercepts be dropped in the plot?

spar Should graphical parmeters be set with par?

formula See bamlss.frame.

train, test Data frames used for training and testing the model..

... For function opt\_boost(), arguments passed to bamlss.engine.setup. for

function boost\_summary() arguments passed to function print.boost\_summary().

#### Value

For function boost\_summary() a list containing information on selection frequencies etc. For function opt\_boost() and opt\_boostm() a list containing the following objects:

fitted.values A named list of the fitted values based on the last boosting iteration of the mod-

eled parameters of the selected distribution.

parameters A matrix, each row corresponds to the parameter values of one boosting itera-

tion.

boost\_summary The boosting summary which can be printed and plotted.

## WARNINGS

The function does not take care of variable scaling for the linear parts! This must be done by the user, e.g., one option is to use argument scale.d in function bamlss.frame, which uses scale.

Function opt\_boost() does not select the optimum stopping iteration! The modified likelihood based algorithm implemented in function opt\_boostm() is still experimental!

opt\_Cox

Cox Model Posterior Mode Estimation

### **Description**

This function computes posterior mode estimates of the parameters of a flexible Cox model with structured additive predictors using a Newton-Raphson algorithm. Integrals are solved numerically. Moreover, optimum smoothing variances are computed using a stepwise optimization, see also the details section of function bfit.

### Usage

```
opt_Cox(x, y, start, weights, offset,
  criterion = c("AICc", "BIC", "AIC"),
  nu = 0.1, update.nu = TRUE,
  eps = .Machine$double.eps^0.25, maxit = 400,
```

opt\_Cox

```
verbose = TRUE, digits = 4, ...)

cox_mode(x, y, start, weights, offset,
    criterion = c("AICc", "BIC", "AIC"),
    nu = 0.1, update.nu = TRUE,
    eps = .Machine$double.eps^0.25, maxit = 400,
    verbose = TRUE, digits = 4, ...)
```

## **Arguments**

The x list, as returned from function bamlss.frame and transformed by function Х surv\_transform, holding all model matrices and other information that is used for fitting the model. The model response, as returned from function bamlss.frame. У start A named numeric vector containing possible starting values, the names are based on function parameters. weights Prior weights on the data, as returned from function bamlss.frame. offset Can be used to supply model offsets for use in fitting, returned from function bamlss.frame. criterion Set the information criterion that should be used, e.g., for smoothing variance selection. Options are the corrected AIC "AICc", the "BIC" and "AIC". Calibrates the step length of parameter updates of one Newton-Raphson update. nu Should the updating step length be optimized in each iteration of the backfitting update.nu algorithm. The relative convergence tolerance of the backfitting algorithm. eps The maximum number of iterations for the backfitting algorithm maxit Print information during runtime of the algorithm. verbose Set the digits for printing when verbose = TRUE. digits Currently not used.

#### Value

A list containing the following objects:

A named list of the fitted values of the modeled parameters of the selected distribution.

The estimated set regression coefficients and smoothing variances.

edf The equivalent degrees of freedom used to fit the model.

logLik The value of the log-likelihood.

logPost The value of the log-posterior.

hessian The Hessian matrix evaluated at the posterior mode.

converged Logical, indicating convergence of the backfitting algorithm.

time The runtime of the algorithm.

Implicit Stochastic Gradient Descent Optimizer

# Description

This optimizer performs an implicit stochastic gradient descent algorithm. It is mainly used within a bamlss call.

# Usage

## **Arguments**

X	For function boost() the x list, as returned from function bamlss. frame, holding all model matrices and other information that is used for fitting the model.
У	The model response, as returned from function bamlss.frame.
family	A bamlss family object, see family.bamlss.
weights	Prior weights on the data, as returned from function bamlss.frame.
offset	Can be used to supply model offsets for use in fitting, returned from function bamlss.frame.
gammaFun	Function specifying the step length.
shuffle	Should the data be shuffled?
CFun	Hessian approximating function.
start	Vector of starting values.
i.state	Added to gammaFUN().

## **Details**

tpf

opt\_isgd 81

#### Value

For function opt\_isgd() a list containing the following objects:

fitted.values A named list of the fitted values based on the last iteration of the modeled pa-

rameters of the selected distribution.

parameters A matrix, each row corresponds to the parameter values of one iteration.

sgd. summary The summary of the stochastic gradient descent algorithm which can be printed

and plotted.

# Warning

CAUTION: Arguments weights and offset are not implemented yet!

parameters

Extract or Initialize Parameters for BAMLSS

### **Description**

The function either sets up a list of all parameters of a bamlss.frame, which can be used for setting up models, or extracts the estimated parameters of a bamlss object.

## Usage

```
parameters(x, model = NULL, start = NULL,
  fill = c(0, 1e-04), list = FALSE,
  simple.list = FALSE, extract = FALSE,
  ...)
```

### **Arguments**

Х	A bamlss.frame or bamlss object.
model	The model name for which parameters should be initialized or extracted.
start	A named numeric vector which should be used when creating the parameter list. See also function link{set.starting.values}
fill	Numeric, when setting up a parameter list, the values the should be used for regression coefficients (first element of fill) and for smoothing variances (second element of fill).
list	Should the function return a list of all parameters?
simple.list	Should the names of parameter vectors be dropped?
extract	Should parameters of a bamlss.frame be extracted or initialized?
	Currently not used.

#### **Details**

Parameters for BAMLSS are used for optimizer functions in function bamlss. The function is useful for initializing all parameters given a bamlss.frame (which is done internally in function bamlss), but also for extracting all estimated parameters of some optimizer.

The naming convention of the parameter list is used by a couple of functions in this package. For each parameter of the modeled distribution, e.g., gaussian\_bamlss has parameters "mu" and "sigma", a list element is created. These elements the contain the list of all model term parameters.

pathplot 83

Parametric model terms are indicated with "p" and smooth model terms with "s". If the design matrix of a model term in the x list of a bamlss.frame does not contain any columns names, then the parameters are named with a leading "b", otherwise the column names of the design matrix are used. Smoothing variances parameter vectors are named with a leading "tau2".

The naming convention is useful when setting up new model fitting engines for bamlss and is used, e.g., by bfit and GMCMC, which are based on parameter state list objects as provided by function bamlss.engine.setup.

#### Value

A named list of all parameters of a bamlss. frame or bamlss object.

#### See Also

```
bamlss.frame, bamlss, opt_bfit, sam_GMCMC, get.par, set.par
```

# **Examples**

```
## Create a "bamlss.frame"
set.seed(123)
d <- GAMart()
bf <- bamlss.frame(num ~ s(x1) + te(lon,lat), data = d)

## Create list of all parameters from "bamlss.frame".
p <- parameters(bf, list = TRUE)
str(p)

## Not run: ## Estimate model.
f <- list(num ~ s(x1) + te(lon,lat), sigma ~ s(x1))
b <- bamlss(f, data = d, sampler = FALSE)

## Extract estimated parameters.
parameters(b)
parameters(b, list = TRUE)

## End(Not run)</pre>
```

pathplot

Plot Coefficients Paths

## **Description**

This is a simple wrapper function to plot coefficients paths obtained from the boosting optimizer function boost and the LASSO optimizer lasso.

## Usage

```
pathplot(object, ...)
```

84 plot.bamlss

### **Arguments**

```
object An object of class "bamlss".

... Arguments passed to boost_plot or lasso_plot.
```

boost_plot, lasso_plot
```

plot.bamlss

Plotting BAMLSS

# Description

Plotting methods for objects of class "bamlss" and "bamlss.results", which can be used for producing effect plots of model terms, trace plots of samples or residual plots. Note that effect plots of model terms with more than two covariates are not supported, for this purpose use function predict.bamlss.

# Usage

```
## S3 method for class 'bamlss'
plot(x, model = NULL, term = NULL,
   which = "effects", parameters = FALSE,
   ask = dev.interactive(), spar = TRUE, ...)

## S3 method for class 'bamlss.results'
plot(x, model = NULL, term = NULL,
   ask = dev.interactive(), scale = 1, spar = TRUE, ...)
```

# Arguments

Х	An object of class "bamlss" or "bamlss.results".
model	Character or integer. For which model should the plots be created?
term	Character or integer. For which model term should a plot be created?
which	Character or integer, selects the type of plot: "effects" produces effect plots of smooth model terms, "samples" shows trace plots of samples, "hist-resid" shows a histogram of residuals (see also residuals.bamlss for the different available types), "qq-resid" shows a quantile-quantile plot of residuals, "scatter-resid" shows a scatter plot of residuals with fitted values for the distribution mean (if available in the family object), "max-acf" shows an acf plot of the maximum autocorrelation of all parameter samples.
parameters	For trace plots of parameters, should corresponding parameter values as returned from an optimizer function (e.g., opt_bfit) be added as horizontal lines?
ask	For multiple plots, the user is asked to show the next plot.

plot2d 85

scale	If set to 1, effect plots all have the same scale on the y-axis. If set to 0 each effect plot has its own scale for the y-axis.
spar	Should graphical parameters be set?
• • •	Arguments to be passed to plot2d, plot3d, sliceplot, plotblock, plotmap and residuals.bamlss.

## See Also

bamlss, results.bamlss.default, residuals.bamlss.

## **Examples**

```
## Not run: ## Generate some data.
d <- GAMart()</pre>
## Model formula.
f <- list(
  num \sim s(x1) + s(x2) + s(x3) + te(lon, lat),
  sigma \sim s(x2) + te(lon, lat)
## Estimate model.
b <- bamlss(f, data = d)</pre>
## Effect plots
plot(b, ask = FALSE)
plot(b, model = "mu")
plot(b, model = "sigma", term = "te(lon,lat)")
## Trace plots.
plot(b, which = "samples")
## Residual plots.
plot(b, which = 3:4)
## End(Not run)
```

plot2d

Plot 2D Effects

# Description

Function to plot simple 2D graphics for univariate effects/functions.

# Usage

```
plot2d(x, residuals = FALSE, rug = FALSE, jitter = TRUE,
  col.residuals = NULL, col.lines = NULL, col.polygons = NULL,
  col.rug = NULL, c.select = NULL, fill.select = NULL,
```

86 plot2d

```
data = NULL, sep = "", month = NULL, year = NULL,
step = 12, shift = NULL, trans = NULL,
scheme = 2, s2.col = NULL, grid = 50, ...)
```

#### **Arguments**

Х

A matrix or data frame, containing the covariate for which the effect should be plotted in the first column and at least a second column containing the effect. Another possibility is to specify the plot via a formula, e.g. y ~ x, see the examples. x may also be a character file path to the data to be used for plotting.

residuals

If set to TRUE, residuals may also be plotted if available. Residuals must be supplied as an attribute named "residuals", which is a matrix or data frame where the first column is the covariate and the second column the residuals.

rug

Add a rug to the plot.

jitter

If set to TRUE a jittered rug plot is added.

col.residuals

The color of the partial residuals.

col.lines

The color of the lines.

col.polygons

Specify the background color of polygons, if x has at least 3 columns, i.e. col-

umn 2 and 3 can form one polygon.

col.rug

Specify the color of the rug representation.

c.select

Integer vector of maximum length of columns of x, selects the columns of the resulting data matrix that should be used for plotting. E.g. if x has 5 columns, then c. select = c(1, 2, 5) will select column 1, 2 and 5 for plotting. Note that first element of c. select should always be the column that holds the variable for the x-axis.

fill.select

Integer vector, select pairwise the columns of the resulting data matrix that should form one polygon with a certain background color specified in argument col. E.g. x has three columns, or is specified with formula  $f1 + f2 \sim x$ , then setting fill. select = c(0, 1, 1) will draw a polygon with f1 and f2 as boundaries. If x has five columns or the formula is e.g.  $f1 + f2 + f3 + f4 \sim x$ , then setting fill. select = c(0, 1, 1, 2, 2), the pairs f1, f2 and f3, f4 are selected to form two polygons.

data

If x is a formula, a data. frame or list. By default the variables are taken from environment(x): typically the environment from which plot2d is called. Note that data may also be a character file path to the data.

sep

The field separator character when x or data is a character, see function read. table.

month, year, step

Provide specific annotation for plotting estimation results for temporal variables. month and year define the minimum time point whereas step specifies the type of temporal data with step = 4, step = 2 and step = 1 corresponding to quarterly, half yearly and yearly data.

shift

Numeric constant to be added to the smooth before plotting.

trans

Function to be applied to the smooth before plotting, e.g., to transform the plot to the response scale.

plot2d 87

scheme	Sets the plotting scheme for polygons, possible values are 1 and 2.
s2.col	The color for the second plotting scheme.
grid	Integer, specifies the number of polygons for the second plotting scheme.
	Other graphical parameters, please see the details.

#### **Details**

For 2D plots the following graphical parameters may be specified additionally:

- cex: Specify the size of partial residuals,
- 1ty: The line type for each column that is plotted, e.g. 1ty = c(1, 2),
- 1wd: The line width for each column that is plotted, e.g. 1wd = c(1, 2),
- poly.lty: The line type to be used for the polygons,
- poly.lwd: The line width to be used for the polygons,
- density angle, border: See polygon,
- ...: Other graphical parameters, see function plot.

plot3d

Plot 3D Effects

#### **Description**

Function to plot 3D graphics or image and/or contour plots for bivariate effects/functions.

#### Usage

```
plot3d(x, residuals = FALSE, col.surface = NULL,
  ncol = 99L, swap = FALSE, col.residuals = NULL, col.contour = NULL,
  c.select = NULL, grid = 30L, image = FALSE, contour = FALSE,
  legend = TRUE, cex.legend = 1, breaks = NULL, range = NULL,
  digits = 2L, d.persp = 1L, r.persp = sqrt(3), outscale = 0,
  data = NULL, sep = "", shift = NULL, trans = NULL,
  type = "mba", linear = FALSE, extrap = FALSE,
  k = 40, ...)
```

# **Arguments**

Χ

A matrix or data frame, containing the covariates for which the effect should be plotted in the first and second column and at least a third column containing the effect. Another possibility is to specify the plot via a formula, e.g. for simple plotting of bivariate surfaces  $z \sim x + y$ , see the examples. x may also be a character file path to the data to be used for plotting.

residuals

If set to TRUE, residuals may also be plotted if available. Residuals must be supplied as an attribute named "residuals", which is a matrix or data frame where the first two columns are covariates and the third column the residuals.

col.surface

The color of the surface, may also be a function, e.g. col.surface = heat.colors. the number of different colors that should be generated, if col.surface is a

ncol

function.

plot3d 89

swap If set to TRUE colors will be represented in reverse order.

col.residuals The color of the partial residuals, or if contour = TRUE the color of the contour

lines.

col. contour The color of the contour lines.

c.select Integer vector of maximum length of columns of x, selects the columns of

the resulting data matrix that should be used for plotting. E.g. if x has 5 columns, then c.select = c(1, 2, 5) will select column 1, 2 and 5 for plotting. If c.select = 95 or c.select = 80, function plot3d will search for the corresponding columns to plot a 95% or 80% confidence surfaces respectively. Note that if e.g. c.select = c(1, 2), plot3d will use columns 1 + 2 and 2 + 2

for plotting.

grid The grid size of the surface(s).

image If set to TRUE, an image.plot is drawn. contour If set to TRUE, a contour plot is drawn.

legend If image = TRUE an additional legend may be added to the plot.

cex.legend The expansion factor for the legend text, see text.

breaks A set of breakpoints for the colors: must give one more breakpoint than ncol.

range Specifies a certain range values should be plotted for.

digits Specifies the legend decimal places.
d.persp See argument d in function persp.
r.persp See argument r in function persp.

outscale Scales the outer ranges of x and z limits used for interpolation.

data If x is a formula, a data.frame or list. By default the variables are taken

from environment(x): typically the environment from which plot3d is called.

Note that data may also be a character file path to the data.

sep The field separator character when x or data is a character, see function read. table.

shift Numeric constant to be added to the smooth before plotting.

trans Function to be applied to the smooth before plotting, e.g., to transform the plot

to the response scale.

type Character, which type of interpolation method should be used. The default is

type = "akima", see function interp. The two other options are type = "mba", which calls function mba.surf of package MBA, or type = "mgcv", which uses a spatial smoother withing package mgcv for interpolation. The last option is definitely the slowest, since a full regression model needs to be estimated.

linear Logical, should linear interpolation be used withing function interp?

extrap Logical, should interpolations be computed outside the observation area (i.e.,

extrapolated)?

k Integer, the number of basis functions to be used to compute the interpolated

surface when type = "mgcv".

... Parameters passed to colorlegend if an image plot with legend is drawn, also

other graphical parameters, please see the details.

90 plot3d

### **Details**

For 3D plots the following graphical parameters may be specified additionally:

- cex: Specify the size of partial residuals,
- col: It is possible to specify the color for the surfaces if se > 0, then e.g. col = c("green", "black", "red"),
- pch: The plotting character of the partial residuals,
- ...: Other graphical parameters passed functions persp, image.plot and contour.

### Note

Function plot3d can use the **akima** package to construct smooth interpolated surfaces, therefore, package **akima** needs to be installed. The **akima** package has an ACM license that restricts applications to non-commercial usage, see

```
https://www.acm.org/publications/policies/software-copyright-notice
```

Function plot3d prints a note referring to the ACM license. This note can be suppressed by setting options("use.akima" = TRUE)

```

plotblock

Factor Variable and Random Effects Plots

### **Description**

Function to plot effects for model terms including factor, or group variables for random effects.

92 plotblock

#### Usage

```
plotblock(x, residuals = FALSE, range = c(0.3, 0.3),
  col.residuals = "black", col.lines = "black", c.select = NULL,
  fill.select = NULL , col.polygons = NULL, data = NULL,
  shift = NULL, trans = NULL, labels = NULL, ...)
```

### **Arguments**

Х

Either a list of length of the unique factors, where each list element contains the estimated effects for one factor as a matrix, or one data matrix with first column as the group or factor variable. Also formulas are accepted, e.g it is possible to specify the plot with  $f \sim x$  or  $f1 + f2 \sim x$ . By convention, the covariate for which effects should be plotted, is always in the first column in the resulting data matrix, that is used for plotting, i.e. in the second formula example, the data matrix is cbind(x, f1, f2), also see argument c.select and fill.select.

residuals

If set to TRUE, residuals will be plotted if available. Residuals may be set as an attribute of x named "residuals", where the residuals must be a matrix with first column specifying the covariate, and second column the residuals that should be plotted.

range

Numeric vector, specifying the left and right bound of the block.

col.residuals

The color of the partial residuals.

col.lines

Vector of maximum length of columns of x minus 1, specifying the color of the lines.

c.select

Integer vector of maximum length of columns of x, selects the columns of the resulting data matrix that should be used for plotting. E.g. if x has 5 columns, then c.select = c(1, 2, 5) will select column 1, 2 and 5 for plotting. Note that first element of c.select should always be 1, since this is the column of the covariate the effect is plotted for.

fill.select

Integer vector, select pairwise the columns of the resulting data matrix that should form one polygon with a certain background color specified in argument col. E.g. x has three columns, or is specified with formula  $f1 + f2 \sim x$ , then setting fill.select = c(0, 1, 1) will draw a polygon with f1 and f2 as boundaries. If x has five columns or the formula is e.g.  $f1 + f2 + f3 + f4 \sim x$ , then setting fill.select = c(0, 1, 1, 2, 2), the pairs f1, f2 and f3, f4 are selected to form two polygons.

col.polygons

Specify the background color for the upper and lower confidence bands, e.g. col = c("green", "red").

data

If x is a formula, a data.frame or list. By default the variables are taken from environment(x): typically the environment from which plotblock is called.

shift

Numeric constant to be added to the smooth before plotting.

trans

Function to be applied to the smooth before plotting, e.g., to transform the plot

to the response scale.

labels

Character, labels for the factor levels.

. . .

Graphical parameters, please see the details.

plotblock 93

### **Details**

Function plotblock draws for every factor or group the effect as a "block" in one graphic, i.e., similar to boxplots, estimated fitted effects, e.g., containing quantiles of MCMC samples, are drawn as one block, where the upper lines represent upper quantiles, the middle line the mean or median, and lower lines lower quantiles, also see the examples. The following graphical parameters may be supplied additionally:

- cex: Specify the size of partial residuals,
- 1ty: The line type for each column that is plotted, e.g. 1ty = c(1, 2),
- lwd: The line width for each column that is plotted, e.g. lwd = c(1, 2),
- poly.lty: The line type to be used for the polygons,
- poly.lwd: The line width to be used for the polygons,
- density angle, border: See polygon,
- . . .: Other graphical parameters, see function plot.

plotblock(y ~ fac, data = d)
plotblock(cbind(y - 0.1, y + 0.1) ~ fac, data = d)</pre>
```

plotmap

Plot Maps

## **Description**

The function takes a list polygons and draws the corresponding map. Different colors for each polygon can be used.

# Usage

```
plotmap(map, x = NA, id = NULL, select = NULL,
  legend = TRUE, names = FALSE, values = FALSE, ...)
```

## **Arguments**

map	The map to be plotted, usually an object that inherits from SpatialPolygons, but may also be a list of polygons, i.e., each list entry is a matrix with x- and y-coordinates.
X	A vector, data.frame or matrix. In the latter case $x$ should have two columns, one column that is the region identifier and one that contains the values to be plotted. In case $x$ is a data.frame, the function searches for "character" or "factor" columns for the region identifier. If $x$ is a matrix, the second column of $x$ is supposed to be the region identifier. If $x = NA$ and map is an object of class "SpatialPolygonsDataFrame" only the polygons will be plotted without using the data.
id	If argument x is a vector, argument id should contain the region identifier vector.
select	Select the column of the data in x which should be used for plotting, may be an integer or character with the corresponding column name.
legend	Should a color legend be added to the plot, see also function colorlegend.
names	If set to TRUE the name for each polygon will also be plotted at the centroids of the corresponding polygons.
values	If set to TRUE the corresponding values for each polygon will also be plotted at the centroids of the polygons.
• • •	Arguments to be passed to colorlegend and others, e.g. change the border of the polygons and density (mdensity for missing regions in id), see polygon.

 lrange = c(0, 60)
```

predict.bamlss

**BAMLSS Prediction** 

#### **Description**

Takes a fitted bamlss object and computes predictions. Predictions can be based on estimated parameters of optimizer functions or on samples returned from sampler functions. It is possible to compute predictions on multiple cores using the parallel and to chunk predictions to save computation time and memory storage. Predictions can be computed for full distributional parameters or specific model terms. If a link{bamlss} model was fitted on multiple cores, i.e., the samples are provided as link{mcmc.list} where each list entry represents samples from one core, function predict.bamlss() computes combined predictions based on samples of all cores.

96 predict.bamlss

#### Usage

```
## S3 method for class 'bamlss'
predict(object, newdata, model = NULL, term = NULL,
    match.names = TRUE, intercept = TRUE, type = c("link", "parameter"),
    FUN = function(x) { mean(x, na.rm = TRUE) }, trans = NULL,
    what = c("samples", "parameters"), nsamps = NULL,
    verbose = FALSE, drop = TRUE,
    cores = NULL, chunks = 1, ...)
```

#### **Arguments**

object An object of class "bamlss"

newdata A data frame or list containing the values of the model covariates at which pre-

dictions are required. Note that depending on argument term, only covariates

that are needed by the corresponding model terms need to be supplied.

model Character or integer, specifies the model for which predictions should be com-

puted.

term Character or integer, specifies the model terms for which predictions are re-

quired. Note that, e.g., term = c("s(x1)", "x2") will compute the combined

prediction s(x1) + x2.

match.names Should partial string matching be used to select the terms for prediction. Note

that, e.g., term = "x1" will select all terms including "x1" if match.names =

TRUE.

intercept Should the intercept be included?

type If type = "link" the predictor of the corresponding model is returned. If type

= "parameter" predictions on the distributional parameter scale are returned.

FUN A function that should be applied on the samples of predictors or parameters,

depending on argument type.

trans A transformer function or named list of transformer functions that computes

transformed predictions. If trans is a list, the list names must match the names

of the parameters of the bamlss.family.

what Predictions can be computed from samples or estimated parameters of optimizer

functions. If no samples are available the default is to use estimated parameters.

nsamps If the fitted bamlss object contains samples of parameters, computing predic-

tions may take quite some time. Therefore, to get a first feeling it can be useful to compute predictions only based on nsamps samples, i.e., nsamps specifies the

number of samples which are extracted on equidistant intervals.

verbose If predictions are chunked, information on the prediction process can be printed.

drop If predictions for only one model are returned, the list structure is dropped.

cores Specifies the number of cores that should be used for prediction. Note that this

functionality is based on the parallel package.

chunks Should computations be split into chunks? Prediction is then processed sequen-

tially.

... Arguments passed to prediction functions that are part of a bamlss.family ob-

ject, i.e., the objects has a \$predict() function that should be used instead.

predict.bamlss 97

### Value

Depending on arguments model, FUN and the structure of the bamlss model, a list of predictions or simple vectors or matrices of predictions.

randomize

Transform Smooth Constructs to Random Effects

# Description

The transformer function takes a bamlss.frame object and transforms all smooth.constructs into a random effects representation. Note that this is only possible for smooth terms with a single smoothing variance. The function is based on function smooth2random.

# Usage

```
trans_random(x)
randomize(x)
```

### **Arguments**

Χ

Object returned from function bamlss.frame.

#### **Details**

The decomposition is achieved by a spectral decomposition of the penalty and design matrix by finding a basis of the null space of the penalty matrix. This feature is used, e.g., for the JAGS sampler function. For more details see also jagam.

# Value

A transformed bamlss.frame. To each smooth.construct model term an element named "Xf", the fixed effects design matrix, and an element "rand\$Xr", the random effects design matrix, is added. In addition, for re-transforming parameters elements "trans.U" and "trans.D" are supplied. See also function smooth2random.

*rb* 99

residuals.bamlss

Compute BAMLSS Residuals

# Description

Function to compute quantile and response residuals.

## Usage

```
## S3 method for class 'bamlss'
residuals(object, type = c("quantile", "response"),
   nsamps = NULL, ...)

## S3 method for class 'bamlss.residuals'
plot(x, which = c("hist-resid", "qq-resid", "wp"),
   spar = TRUE, ...)
```

residuals.bamlss 101

# Arguments

object	An object of class "bamlss".
type	The type of residuals wanted, possible types are "quantile" residuals and "response" residuals.
nsamps	If the fitted bamlss object contains samples of parameters, computing residuals may take quite some time. Therefore, to get a first feeling it can be useful to compute residuals only based on nsamps samples, i.e., nsamps specifies the number of samples which are extracted on equidistant intervals.
X	Object returned from function residuals.bamlss().
which	Should a histogram with kernel density estimates be plotted, a qq-plot or a worm plot?
spar	Should graphical parameters be set by the plotting function?
	For function residuals.bamlss() arguments passed to possible \$residuals() functions that may be part of a bamlss.family. For function plot.bamlss.residuals() arguments passed to function hist.default and qqnorm.default.

#### **Details**

Response residuals are the raw residuals, i.e., the response data minus the fitted distributional mean. If the bamlss.family object contains a function mu(par, ...), then raw residuals are computed with y - mu(par) where par is the named list of fitted values of distributional parameters. If mu(par, ...) is missing, then the fitted values of the first distributional parameter are used.

Randomized quantile residuals are based on the cumulative distribution function of the bamlss.family object, i.e., the \$p(y, par, ...) function.

# Value

A vector of residuals.

Compute BAMLSS Results for Plotting and Summaries

# Description

The results function combines estimated parameters and/or samples with the bamlss.frame and computes the data that can be used, e.g., for creating effect plots or summary statistics. The function is usually used internally within bamlss. The object returned is of class "bamlss.results", which has a plotting method, see plot.bamlss.results.

# Usage

```
results.bamlss.default(x, what = c("samples", "parameters"), grid = -1, nsamps = NULL, burnin = NULL, thin = NULL, ...)
```

## **Arguments**

x	A bamlss.frame which has estimated parameters or samples. See also bfit and $\ensuremath{GMCMC}.$
what	Should the results data be prepared using estimated parameters or samples?
grid	Integer, sets the number of grid points for univariate functions to be used for creating results data, e.g., for plotting. This is more efficient when using data sets with a large number of unique covariate values. If negative suitable defaults are chosen.
nsamps	Integer, if results are computed using parameter samples, this argument controls the number of samples that should be used, e.g., if nsamps = 100 only 100 samples with equidistant intervals are selected. Basically similar to argument thin.
burnin	Integer, sets the number of samples that should be dropped from the beginning of the MCMC chain when creating results.
thin	Integer, should the MCMC chain be thinned additionally?
	Currently not used.

### Value

An object of class "bamlss.results".

### See Also

```

## Estimate model with no results.
b <- bamlss(num ~ s(x1) + s(x2) + s(x3),
    data = d, results = FALSE)

## Compute model results
a <- results.bamlss.default(b)

## Plot results for smooth terms.
plot(a)

## End(Not run)</pre>
```

rmf

Remove Special Characters

# Description

A simple helper function that removes special characters from a character string.

# Usage

rmf(x)

## **Arguments**

Χ

A character string.

### Value

A character string with special characters removed.

```
rmf("ba*&m^1$$:s.s")
```

s2 105

s2

# Description

This is a simple wrapper function to define special smooth terms in BAMLSS formulae. The function calls the smooth term constructor function s. The return value of s is only slightly modified, such that function bamlss.frame identifies this term as a special term and uses the appropriate (internal) infrastructures.

This structure is useful when the model term structure is, e.g., not a linear combination of a design matrix and coefficients. See the example section of function bfit on how to use this setup.

# Usage

```
s2(...)
```

### **Arguments**

.. Arguments passed to function s.

### Value

Slightly modified return value of function s.

#### See Also

```
bamlss, bamlss.frame, bamlss.formula, opt_bfit
```

# **Examples**

```
print(names(s(x)))
print(names(s2(x)))
```

samples

**Extract Samples** 

# Description

Generic function to extract samples from objects.

106 samples

# Usage

```
## Generic.
samples(object, ...)
## Method for "bamlss" objects.
## S3 method for class 'bamlss'
samples(object, model = NULL, term = NULL,
    combine = TRUE, drop = TRUE, burnin = NULL,
    thin = NULL, coef.only = FALSE, ...)
```

## **Arguments**

object	An object for which samples should be extracted.
model	Character or integer, specifies the model for which samples should be extracted.
term	Character or integer, specifies the term for which samples should be extracted.
combine	Samples stored as a mcmc.list, e.g., when a model is estimated on multiple cores, can be combined into one large sample matrix.
drop	If there is only one model for which samples should be extracted, should the list structure be dropped?
burnin	Integer, specifies the number of samples that should be withdrawn as a burn-in phase.
thin	Integer, specifies the step length of samples that should be extracted, e.g., thin = 10 mean that only every 10th sample is returned.
coef.only	Logical, should only samples of model coefficients be returned?
	Other arguments.

samplestats 107

samplestats Sampling Statistics
---------------------------------

# Description

The function computes the average the log-likelihood, log-posterior, the deviance information criterion and estimated degrees of freedom from samples of, e.g., a bamlss object.

## Usage

```
samplestats(samples, x = NULL, y = NULL,
family = NULL, logLik = FALSE, ...)
```

## **Arguments**

samples	An object of class "mcmc.list" or "bamlss" which contains MCMC samples.
x	The x list as returned by function bamlss.frame.
у	The model response, as returned by function bamlss.frame
family	A bamlss.family object.
logLik	Logical, should the log-likelihood be computed, may take some time!
	Currently not used.

#### **Details**

If the log-likelihood is not available in the samples, the function tries to compute the information. Depending on the complexity of the model, this may take some time. Computations are based on the \$d() or \$loglik() function of the bamlss.family object.

If a bamlss.family object contains a function \$p2d() or \$p2loglik(), which computes the log-likelihood from parameters, these functions are used for computation.

### Value

A list with the following entries (if available):

logLik	The average log-likelihood.
logPost	The average log-posterior.
DIC	The deviance information criterion
pd	The estimated degrees of freedom.

## End(Not run)</pre>
```

sam\_BayesX

Markov Chain Monte Carlo for BAMLSS using BayesX

### Description

This sampler function for BAMLSS is an interface to the **BayesX** (https://www.uni-goettingen.de/de/bayesx/550513. command-line binary from R. The sampler is based on the command line version and functions provided in the **BayesXsrc** package, which can be installed using function get\_BayesXsrc().

## Usage

```
## Sampler functions:
sam_BayesX(x, y, family, start = NULL, weights = NULL, offset = NULL,
 data = NULL, control = BayesX.control(...), ...)
BayesX(x, y, family, start = NULL, weights = NULL, offset = NULL,
  data = NULL, control = BayesX.control(...), ...)
## Sampler control:
BayesX.control(n.iter = 1200, thin = 1, burnin = 200,
  seed = NULL, predict = "light", model.name = "bamlss",
 data.name = "d", prg.name = NULL, dir = NULL,
  verbose = FALSE, show.prg = TRUE, modeonly = FALSE, ...)
## Special BayesX smooth term constructor.
sx(x, z = NULL, bs = "ps", by = NA, ...)
## Special BayesX tensor product smooth term constructor.
tx(..., bs = "ps", k = -1,
  ctr = c("center", "main", "both", "both1", "both2",
    "none", "meanf", "meanfd", "meansimple", "nullspace"),
 xt = NULL, special = TRUE)
```

sam\_BayesX 109

```
tx2(...)
tx3(..., bs = "ps", k = c(10, 5),
 ctr = c("main", "center"),
 xt = NULL, special = TRUE)
tx4(..., ctr = c("center", "main", "both", "both1", "both2"))
## Smooth constructors and predict matrix.
## S3 method for class 'tensorX.smooth.spec'
smooth.construct(object, data, knots, ...)
## S3 method for class 'tensorX.smooth'
Predict.matrix(object, data)
## S3 method for class 'tensorX3.smooth.spec'
smooth.construct(object, data, knots, ...)
## S3 method for class 'tensorX3.smooth'
Predict.matrix(object, data)
## Family object for quantile regression with BayesX.
quant_bamlss(prob = 0.5)
## Download the newest version of BayesXsrc.
get_BayesXsrc(dir = NULL, install = TRUE)
```

# Arguments x

	holding all model matrices and other information that is used for fitting the model. For function sx() arguments x and z specify the variables the smooth should be a function of.
у	The model response, as returned from function bamlss.frame.
z	Second variable in a sx() term.
family	A <b>bamlss</b> family object, see family.bamlss.
start	A named numeric vector containing possible starting values, the names are based on function parameters.
weights	Prior weights on the data, as returned from function bamlss.frame.
offset	Can be used to supply model offsets for use in fitting, returned from function bamlss.frame.
data	The model frame that should be used for modeling. Note that argument data needs not to be specified when the BayesX() sampler function is used with bamlss. For the smooth constructor for $tx()$ terms, see function $smooth.construct$ .
control	List of control arguments to be send to BayesX. See below.
n.iter	Sets the number of MCMC iterations.
thin	Defines the thinning parameter for MCMC simulation. E.g., thin = 10 means, that only every 10th sampled parameter will be stored.
burnin	Sets the burn-in phase of the sampler, i.e., the number of starting samples that should be removed.

For function BayesX() the x list, as returned from function bamlss.frame,

110 sam\_BayesX

seed Sets the seed.

predict Not supported at the moment, do not modify!

model.name The name that should be used for the model when calling **BayesX**.

data.name The name that should be used for the data set when calling **BayesX**.

prg.name The name that should be used for the .prg file that is send to **BayesX**.

dir Specifies the directory where **BayesX** should store all output files. For function

get\_BayesXsrc(), the directory where **BayesXsrc** should be stored.

verbose Print information during runtime of the algorithm.

show.prg Show the **BayesX** .prg file.

mode only Should only the posterior mode be compute, note that this is done using fixed

smoothing parameters/variances.

bs A character string, specifying the basis/type which is used for this model term.

by A by variable for varying coefficient model terms.

k The dimension(s) of the bases used to represent the tx() smooth term.

.. Not used in BayesX.control. For function sx() any extra arguments that

should be passed to **BayesX** for this model term can be specified here. For function tx(), all variables the smooth should be a function of are specified here. For function sam\_BayesX() all arguments that should be passed to BayesX.control.

ctr Specifies the type of constraints that should be applied. "main", both main

effects should be removed; "both", both main effects and varying effects should

be removed; "none", no constraint should be applied.

xt A list of extra arguments to be passed to **BayesX**.

special Should the tx() model term be treated as a special smooth. This must be set to

TRUE if using the sam\_BayesX sampler and should be set to FALSE, e.g., when

using the sam\_GMCMC sampler.

object, knots See, function smooth.construct.

prob Numeric, specifies the quantile to be modeled, see the examples.

install Should package **BayesXsrc** be installed?

#### **Details**

Function sam\_BayesX() writes a **BayesX** .prg file and processes the data. Then, the function call the **BayesX** binary via function run.bayesx() of the **BayesXsrc** package. After the **BayesX** sampler has finished, the function reads back in all the parameter samples that can then be used for further processing within bamlss, i.a.

The smooth term constructor functions s and te can be used with the sam\_BayesX() sampler. When using te note that only one smoothing variance is estimated by **BayesX**.

For anisotropic penalties use function tx() and tx3(), the former currently supports smooth functions of two variables, while tx3() is supposed to model space-time interactions. Note that in tx3() the first variable represents time and the 2nd and 3rd variable the coordinates in space.

sam\_BayesX 111

#### Value

Function sam\_BayesX() returns samples of parameters. The samples are provided as a mcmc matrix.

Function BayesX.control() returns a list with control arguments for BayesX.

Function sx() a list of class "xx.smooth.spec" and "no.mgcv", where "xx" is a basis/type identifying code given by the bs argument.

Function tx() and tx2() a list of class tensorX.smooth.spec.

#### Note

Note that this interface is still experimental and needs the newest version of the **BayesX** source code, which is not yet part of the **BayesXsrc** package on CRAN. The newest version can be installed with function get\_BayesXsrc. Note that the function assumes that sh, subversion (svn) and R can be run from the command line!

Note that for setting up a new family object to be used with sam\_BayesX() additional information needs to be supplied. The extra information must be placed within the family object in an named list element named "bayesx". For each parameter of the distribution a character string with the corresponding **BayesX** family name and the equationtype must be supplied. See, e.g., the R code of gaussian\_bamlss how the setup works.

For function sx() the following basis types are currently supported:

- "ps": P-spline with second order difference penalty.
- "mrf": Markov random fields: Defines a Markov random field prior for a spatial covariate, where geographical information is provided by a map object in boundary or graph file format (see function read.bnd, read.gra and shp2bnd), as an additional argument named map.
- "re": Gaussian i.i.d. Random effects of a unit or cluster identification covariate.

Function tx() currently supports smooth terms with two variables.

sam\_Cox

Cox Model Markov Chain Monte Carlo

## **Description**

This sampler function implements a derivative based MCMC algorithm for flexible Cox models with structured additive predictors.

# Usage

```
sam_Cox(x, y, family, start, weights, offset,
  n.iter = 1200, burnin = 200, thin = 1,
  verbose = TRUE, digits = 4, step = 20, ...)

cox_mcmc(x, y, family, start, weights, offset,
  n.iter = 1200, burnin = 200, thin = 1,
  verbose = TRUE, digits = 4, step = 20, ...)
```

#### **Arguments**

Х

The x list, as returned from function bamlss.frame and transformed by function surv\_transform, holding all model matrices and other information that is used for fitting the model.

sam\_Cox 113

у	The model response, as returned from function bamlss.frame.
family	A <b>bamlss</b> family object, see family.bamlss. In this case this is the cox_bamlss family object.
start	A named numeric vector containing possible starting values, the names are based on function parameters.
weights	Prior weights on the data, as returned from function bamlss.frame.
offset	Can be used to supply model offsets for use in fitting, returned from function bamlss.frame.
n.iter	Sets the number of MCMC iterations.
burnin	Sets the burn-in phase of the sampler, i.e., the number of starting samples that should be removed.
thin	Defines the thinning parameter for MCMC simulation. E.g., thin = 10 means, that only every 10th sampled parameter will be stored.
verbose	Print information during runtime of the algorithm.
digits	Set the digits for printing when verbose = TRUE.
step	How many times should algorithm runtime information be printed, divides n.iter.
	Currently not used.

#### **Details**

The sampler uses derivative based proposal functions to create samples of parameters. For time-dependent functions the proposals are based on one Newton-Raphson iteration centered at the last state, while for the time-constant functions proposals can be based on iteratively reweighted least squares (IWLS), see also function GMCMC. The integrals that are part of the time-dependent function updates are solved numerically. In addition, smoothing variances are sampled using slice sampling.

## Value

The function returns samples of parameters. The samples are provided as a mcmc matrix.

sam\_GMCMC

General Markov Chain Monte Carlo for BAMLSS

### **Description**

These functions provide a quite general infrastructure for sampling BAMLSS. The default proposal function is based on iteratively weighted least squares (IWLS), however, each model term may have a different updating function, see the details.

## Usage

```
## Sampler functions:
sam_GMCMC(x, y, family, start = NULL, weights = NULL, offset = NULL,
n.iter = 1200, burnin = 200, thin = 1, verbose = TRUE,
step = 20, propose = "iwlsC_gp", chains = NULL, ...)

GMCMC(x, y, family, start = NULL, weights = NULL, offset = NULL,
n.iter = 1200, burnin = 200, thin = 1, verbose = TRUE,
step = 20, propose = "iwlsC_gp", chains = NULL, ...)

## Propose functions:
GMCMC_iwls(family, theta, id, eta, y, data,
weights = NULL, offset = NULL, ...)
GMCMC_iwlsC(family, theta, id, eta, y, data,
weights = NULL, offset = NULL, zworking, resids, rho, ...)
GMCMC_iwlsC_gp(family, theta, id, eta, y, data,
weights = NULL, offset = NULL, zworking, resids, rho, ...)
GMCMC_slice(family, theta, id, eta, y, data, ...)
```

sam\_GMCMC 115

#### **Arguments**

x For function bfit() the x list, as returned from function bamlss.frame, holding all model matrices and other information that is used for fitting the model. For the updating functions an object as returned from function smooth.construct or smoothCon.

y The model response, as returned from function bamlss.frame.

family A **bamlss** family object, see family.bamlss.

start A named numeric vector containing possible starting values, the names are

based on function parameters.

weights Prior weights on the data, as returned from function bamlss.frame.

offset Can be used to supply model offsets for use in fitting, returned from function

bamlss.frame.

n.iter Sets the number of MCMC iterations.

burnin Sets the burn-in phase of the sampler, i.e., the number of starting samples that

should be removed.

thin Defines the thinning parameter for MCMC simulation. E.g., thin = 10 means,

that only every 10th sampled parameter will be stored.

verbose Print information during runtime of the algorithm.

step How many times should algorithm runtime information be printed, divides n.iter.

propose Sets the propose function for model terms, e.g. for a term s(x) in the model

formula. Per default this is set to "iwlsC", a character pointing to the set of propose functions, see above. Other options are "iwls" and "slice", however, this is more experimental and should not be set by the user. Another option is to pass a full propose function which should be used for each model term, the structure of propose functions is described in the details below. Model terms

may also have different propose functions, see the example section.

chains How many chains should be started? Chains a sampled sequentially!

theta The current state of parameters, provided as a named list. The first level repre-

sents the parameters of the distribution, the second level the parameters of the

 $model\ terms.\ E.g., using\ the\ {\tt gaussian\_bamlss}\ family\ object\ theta \hbox{\tt le"mu"]} \hbox{\tt le"s(x)"]}$ 

extracts the current state of a model term "s(x)" of the "mu" parameter. Extraction is done with the ideacurrent

tion is done with the id argument.

id The parameter identifier, a character vector of length 2. The first character spec-

ifies the current distributional parameter, the second the current model term.

eta The current value of the predictors, provided as a named list, one list entry for

each parameter. The names correspond to the parameter names in the family object, see family.bamlss. E.g., when using the gaussian\_bamlss family object, the current values for the mean can be extracted by eta\\$mu and for the

standard deviation by eta\\$sigma.

data An object as returned from function smooth.construct or smoothCon. The

object is preprocessed by function bamlss.engine.setup.

zworking Preinitialized numeric vector of length(y), only for internal usage.

resids Preinitialized numeric vector of length(y), only for internal usage.

116 sam\_GMCMC

rho An environment, only for internal usage.

... Arguments passed to function bamlss.engine.setup and to the propose functions.

#### **Details**

The sampler function  $sam\_GMCMC()$  cycles through all distributional parameters and corresponding model terms in each iteration of the MCMC chain. Samples of the parameters of a model term (e.g., s(x)) are generated by proposal functions, e.g.  $gMCMC_ivls()$ .

The default proposal function that should be used for all model terms is set with argument propose. For smooth terms, e.g. terms created with function s, if a valid propose function is supplied within the extra xt list, this propose function will be used. This way each model term may have its own propose function for creating samples of the parameters. See the example section.

The default proposal function GMCMC\_iwlsC\_gp allows for general priors for the smoothing variances and general penalty functions. Samples of smoothing variances are computed using slice sampling. Function GMCMC\_iwlsC samples smoothing variances of univariate terms assuming an inverse gamma prior. Terms of higher dimensions use again slice sampling for creating samples of smoothing variances.

Function GMCMC\_iwls is similar to function GMCMC\_iwlsC but uses plain R code.

Function GMCMC\_slice applies slice sampling also for the regression coefficients and is therefore relatively slow.

#### Value

The function returns samples of parameters, depending on the return value of the propose functions other quantities can be returned. The samples are provided as a mcmc matrix. If chains > 1, the samples are provided as a mcmc.list.

sam\_JAGS

Markov Chain Monte Carlo for BAMLSS using JAGS

## **Description**

This sampler function for BAMLSS is an interface to the JAGS library using package rjags. The function basically interprets the bamlss.frame into BUGS code, similar to the jagam function of package mgcv. I.e., the function uses the random effects representation of smooth terms, see the transformer function randomize to generate the BUGS code.

Note that estimating BAMLSS with JAGS is not very efficient. Also note that this function is more experimental and support is only provided for a small number of bamlss.family objects.

Function BUGSeta() therefore computes the code and data for one parameter of the modeled distribution. Function BUGSmodel() then collects all parameter model code and data, which can be send to JAGS.

## Usage

```
## Sampler functions:
sam_JAGS(x, y, family, start = NULL,
    tdir = NULL, n.chains = 1, n.adapt = 100,
    n.iter = 4000, thin = 2, burnin = 1000,
    seed = NULL, verbose = TRUE, set.inits = TRUE,
    save.all = FALSE, modules = NULL, ...)

JAGS(x, y, family, start = NULL,
    tdir = NULL, n.chains = 1, n.adapt = 100,
    n.iter = 4000, thin = 2, burnin = 1000,
    seed = NULL, verbose = TRUE, set.inits = TRUE,
    save.all = FALSE, modules = NULL, ...)

## Function to interpret an additive predictor into BUGS code:
BUGSeta(x, id = NULL, ...)

## Function to interpret the full BAMLSS:
BUGSmodel(x, family, is.stan = FALSE, reference = NULL, ...)
```

#### **Arguments**

Х

For function sam\_JAGS() and BUGSmodel() the x list, as returned from function bamlss.frame, holding all model matrices and other information that is used

118 sam\_JAGS

	for fitting the model. For function $BUGSeta()$ argument x is one element of the x object, i.e., one parameter.
у	The model response, as returned from function bamlss.frame.
family	A bamlss family object, see family.bamlss.
start	A named numeric vector containing possible starting values, the names are based on function parameters.
tdir	The path to the temporary directory that should be used.
n.chains	Specifies the number of sequential MCMC chains that should be run with JAGS.
n.adapt	Specifies the number of iterations that should be used as an initial adaptive phase.
n.iter	Sets the number of MCMC iterations.
thin	Defines the thinning parameter for MCMC simulation. E.g., thin = 10 means, that only every 10th sampled parameter will be stored.
burnin	Sets the burn-in phase of the sampler, i.e., the number of starting samples that should be removed.
seed	Sets the seed.
verbose	Print information during runtime of the algorithm.
set.inits	Should initial values of BAMLSS parameters be provided to JAGS, if available. Set in argument start.
save.all	Should all JAGS files be saved in tdir.
modules	Specify additional modules that should be loaded, see function load.module.
id	Character, the current parameter name for which the BUGS code should be produced.
is.stan	Should the BUGS code be translated to STAN code. Note that this is only experimental.
reference	A character specifying a reference category, e.g., when fitting a multinomial model.
	Currently not used.

### Value

Function  $sam_JAGS()$  returns samples of parameters. The samples are provided as a mcmc matrix. If n.chains > 1, the samples are provided as a mcmc.list.

Function BUGSeta() returns the BUGS model code and preprocessed data for one additive predictor. Function BUGSmodel() then combines all single BUGS code chunks and the data and creates the final BUGS model code that can be send to JAGS.

## Note

Note that for setting up a new family object to be used with sam\_JAGS() additional information needs to be supplied. The extra information must be placed within the family object in an element named "bugs". The following entries should be supplied within the ..\$bugs list:

• "dist". The name of the distribution in BUGS/JAGS model language.

sam\_MVNORM 119

• "eta". The function that computes the BUGS code for one structured additive predictor. Function BUGSeta() is used per default.

- "model". The function that merges all single predictor BUGS model code and data. The default function is BUGSmodel().
- "reparam". A named vector of character strings that specify a re-parametrization.

See also the example code of family.bamlss.

sam\_MVNORM

Create Samples for BAMLSS by Multivariate Normal Approximation

# Description

This sampler function for BAMLSS uses estimated parameters and the Hessian information to create samples from a multivariate normal distribution. Note that smoothing variance uncertainty is not accounted for, therefore, the resulting credible intervals are most likely too narrow.

120 sam\_MVNORM

### Usage

```
sam_MVNORM(x, y = NULL, family = NULL, start = NULL,
    n.samples = 500, hessian = NULL, ...)

MVNORM(x, y = NULL, family = NULL, start = NULL,
    n.samples = 500, hessian = NULL, ...)
```

## **Arguments**

х	The x list, as returned from function bamlss.frame, holding all model matrices and other information that is used for fitting the model. Or an object returned from function bamlss.
У	The model response, as returned from function bamlss.frame.
family	A bamlss family object, see family.bamlss.
start	A named numeric vector containing possible starting values, the names are based on function parameters.
n.samples	Sets the number of samples that should be generated.
hessian	The Hessian matrix that should be used. Note that the row and column names must be the same as the names of the parameters. If hessian = NULL the function uses optim to compute the Hessian if it is not provided within x.
	Arguments passed to function optim.

## Value

Function MVNORM() returns samples of parameters. The samples are provided as a mcmc matrix.

scale2 121

scale2

Scaling Vectors and Matrices

## **Description**

The function scales numeric objects to specific ranges.

# Usage

```
scale2(x, lower = -1.5, upper = 1.5)
```

## **Arguments**

x Numeric, vector or matrix.

lower The upper range.

upper The lower range.

## Value

A scaled numeric vector or matrix, scaled to the range provided in lower and upper.

# **Examples**

```
set.seed(123)
x <- runif(5)
scale2(x, -1, 1)
scale2(x, 0, 10)</pre>
```

simJM

Simulate longitudinal and survival data for joint models

## **Description**

Simulates longitudinal data with normal error and (Cox-type) survival times using the inversion method. The function simJM() is a wrapper specifying all predictors and the resulting data sets. The wrapper calls rJM() to sample the survival times, a modified version of rSurvtime() from the R package CoxFlexBoost.

122 simJM

#### Usage

```
simJM(nsub = 300, times = seq(0, 120, 1), probmiss = 0.75,
  long_setting = "functional",
  alpha_setting = if(nonlinear) "linear" else "nonlinear",
  dalpha_setting = "zero", sigma = 0.3, long_df = 6, tmax = NULL,
  seed = NULL, full = FALSE, file = NULL, nonlinear = FALSE,
  fac = FALSE)

rJM(hazard, censoring, x, r,
  subdivisions = 1000, tmin = 0, tmax,
  file = NULL, ...)
```

## **Arguments**

nsub number of individuals for which longitudinal data and survival times should be

simulated.

times vector of time points at which longitudinal measurements are "sampled".

proportion of longitudinal measurements to be set to missing. Used to induce

sparsity in the longitudinal measurements.

long\_setting Specification of the longitudinal trajectories of the sampled subjects. Preset

specifications are "linear", "nonlinear" and "functional". See Details.

alpha\_setting specification of the association between survival and longitudinal. Preset spec-

ifications are "simple", "linear", "nonlinear" and "nonlinear2". See De-

tails.

dalpha\_setting specification of the association between survival and the derivative of the longi-

tudinal. Work in progress.

sigma standard deviation of the normal error around the true longitudinal measure-

ments.

long\_df number of basis functions from which functional random intercepts are sampled.

tmax For function simJM(), longest possible survival time, observations are censored

after that timepoint. Defaults to max(times) and should not be specified longer than max(times) for longitudinal setting "functional". For function rJM(), lat-

est time point to sample a survival time.

seed numeric scalar setting the random seed.

full logical indicating if only the longitudinal data set should be returned (FALSE) or

additionally also the data for the survival part evaluated on a regular time grid

and the longitudinal data set without longitudinal missings (TRUE).

file name of the data file the generated data set should be stored into (e.g., "sim-

data.RData") or NULL if the dataset should directly be returned in R.

nonlinear If set to TRUE, a nonlinear interaction between alpha and mu is simulated.

fac If set to TRUE, a smooth interaction that varies by a factor is simulated.

hazard complete hazard function to specify the joint model. Time must be the first

argument.

censoring function to compute (random) censoring.

simJM 123

x matrix of sampled covariate values.

r matrix of sampled random coefficients.

subdivisions the maximum number of subintervals for the integration.

tmin earliest time point to sample a survival time.

... further arguments to be passed to hazard or censoring.

#### **Details**

The function simulates longitudinal data basing on the given specification at given times. The full hazard is built from all joint model predictors  $\eta_{\mu}$ ,  $\eta_{\sigma}$ ,  $\eta_{\lambda}$ ,  $\eta_{\gamma}$ ,  $\eta_{\alpha}$  as presented in Koehler, Umlauf, and Greven (2016), see also jm\_bamlss. Survival times are sampled using the inversion method (cf. Bender, Augustin, & Blettner, 2005). Additional censoring and missingness is introduced. The longitudinal information is censored according to the survival information. The user can also specify own predictors and use only rJM to simulate survival times accordingly.

Pre-specified functions for  $\eta_{\mu}$  in long\_setting are for linear

$$\eta_{ui}(t) = 1.25 + r_{1i} + 0.6\sin(x_{2i}) + (-0.01)t + 0.02r_{2i}t$$

, for nonlinear

$$\eta_{\mu i}(t) = 0.5 + r_{1i} + 0.6\sin(x_{2i}) + 0.1(t+1)\exp(-0.075t)$$

and for functional

$$\eta_{\mu i}(t) = 0.5 + r_{1i} + 0.6\sin(x_{2i}) + 0.1(t+1)\exp(-0.075t) + \sum_{k} \beta_{ki}B(t)$$

, where B(.) denotes a B-spline basis function and  $\beta_{ki}$  are the sampled penalized coefficients from gen\_b per person.

Prespecified functions for  $\eta_{\alpha}$  in alpha\_setting are for constant

$$\eta_{\alpha}(t) = 1$$

, for linear

$$\eta_{\alpha}(t) = 1 - 0.015t$$

, for nonlinear

$$\eta_{\alpha}(t) = \cos((time - 20)/20)$$

, and for nonlinear

$$\eta_{\alpha}(t) = \cos((time - 33)/33)$$

Additionally the fixed functions for  $\eta_{\lambda}=0.1(t+2)\exp(-0.075t)$  and  $\eta_{\lambda}=0.1(t+2)\exp(-0.075t)$  are employed.

124 simJM

#### Value

For full = TRUE a list of the three data. frames is returned:

data Simulated dataset in long format including all longitudinal and survival covari-

ates.

data\_grid Dataset of the time-varying survival predictors which are not subject specific,

evaluated at a grid of fixed time points.

data\_full Simulated data set prior to generating longitudinal missings. Useful to assess

the longitudinal fit.

For full = FALSE only the first dataset is returned.

Covariates within these datasets include a subject identifier id, the sampled survival times survtime, the event indicator event, the time points of longitudinally "observed" measurements obstime, the longitudinal response y, the cumulative hazard at the survival time cumhaz, as well as covariates x1, x2, random effects r1, r2, b1, ..., and the true predictors alpha, lambda, gamma, mu, sigma.

simSurv 125

simSurv	Simulate Survival Times	

# **Description**

Function simSurv() and rSurvtime2() simulate arbitrary (Cox-type) survival times using the inversion method. Function simSurv() is a simple wrapper that calls rSurvtime2(). The functions are based on the R package **CoxFlexBoost** implementation rSurvtime() and only slightly modify the code.

## Usage

```
## Simulate a pre-specified survival times data set.
simSurv(n = 300)

## Simulate arbitrary survival times.
rSurvTime2(lambda, x, cens_fct, upper = 1000, ...,
file = NULL, subdivisions = 1000)
```

## **Arguments**

n	The number of individuals for which survival times should be simulated.
lambda	function. Baseline hazard $\lambda(t,x)$ where time must be first argument.
х	matrix. (Sampled) values for covariates (without time).
cens_fct	function. Function to compute (random) censoring.
upper	upper boundary of the interval the random survival times fall into.
	further arguments to be passed to lambda or cens_fct.
file	character. name of the data file the generated data set should be stored into (e.g., "survtimes.RData") or NULL if the dataset should directly be returned in $R$ .
subdivisions	The maximum number of subintervals for the integration.

# **Details**

This is basically a slight modification according the computation of the integral, see the manual page of function rSurvtime() of package CoxFlexBoost for details.

## Value

A data.frame consisting of the observed survival time (time), the non-censoring indicator (event) and further covariates x is returned. If file is specified, the data.frame is additionally stored on the disc.

sliceplot

Plot Slices of Bivariate Functions

## **Description**

This function plots slices from user defined values of bivariate surfaces.

sliceplot 127

# Usage

```
sliceplot(x, y = NULL, z = NULL, view = 1, c.select = NULL,
  values = NULL, probs = c(0.1, 0.5, 0.9), grid = 100,
  legend = TRUE, pos = "topright", digits = 2, data = NULL,
  rawdata = FALSE, type = "mba", linear = FALSE,
  extrap = FALSE, k = 40, rug = TRUE, rug.col = NULL,
  jitter = TRUE, ...)
```

#### **Arguments**

extrap

extrapolated)?

A matrix or data frame, containing the covariates for which the effect should be plotted in the first and second column and at least a third column containing the effect. Another possibility is to specify the plot via a formula, e.g., for simple plotting of bivariate surfaces $z \sim x + y$ , see the examples.
If x is a vector the argument y and z must also be supplied as vectors.
If x is a vector the argument y and z must also be supplied as vectors, z defines the surface given by $z=f(x,y)$ .
Which variable should be used for the x-axis of the plot, the other variable will be used to compute the slices. May also be a character with the name of the corresponding variable.
Integer, selects the column that is used in the resulting matrix to be used as the z argument.
The values of the x or y variable that should be used for computing the slices, if set to NULL, slices will be constructed according to the quantiles, see also argument probs.
Numeric vector of probabilities with values in [0,1] to be used within function quantile to compute the values for plotting the slices.
The grid size of the surface where the slices are generated from.
If set to TRUE, a legend with the values that where used for slicing will be added.
The position of the legend, see also function legend.
The decimal place the legend values should be rounded.
If $x$ is a formula, a data.frame or list. By default the variables are taken from environment( $x$ ): typically the environment from which plot3d is called.
If set to TRUE, the data will not be interpolated, only raw data will be used. This is useful when displaying data on a regular grid.
Character, which type of interpolation method should be used. The default is type = "akima", see function interp. The two other options are type = "mba", which calls function mba.surf of package MBA, or type = "mgcv", which uses a spatial smoother withing package mgcv for interpolation. The last option is definitely the slowest, since a full regression model needs to be estimated.
Logical, should linear interpolation be used withing function interp?

Logical, should interpolations be computed outside the observation area (i.e.,

128 sliceplot

k	Integer, the number of basis functions to be used to compute the interpolated surface when type = "mgcv".
rug	Add a rug to the plot.
jitter	If set to TRUE a jittered rug plot is added.
rug.col	Specify the color of the rug representation.
	Parameters passed to matplot and legend.

#### **Details**

Similar to function plot3d, this function first applies bivariate interpolation on a regular grid, afterwards the slices are computed from the resulting surface.

### Note

Function sliceplot can use the **akima** package to construct smooth interpolated surfaces, therefore, package **akima** needs to be installed. The **akima** package has an ACM license that restricts applications to non-commercial usage, see

```
https://www.acm.org/publications/policies/software-copyright-notice
```

Function sliceplot prints a note referring to the ACM license. This note can be suppressed by setting

```
options("use.akima" = TRUE)
```

smooth.construct

Constructor Functions for Smooth Terms in BAMLSS

## **Description**

The generic function is only a copy of smooth.construct adding a ... argument. For objects of class "bamlss.frame" and "bamlss" the method extracts all smooth model terms, see function bamlss.frame for details on the setup of BAMLSS.

### Usage

```
## Function as in package mgcv
## but with additional dots argument.
smooth.construct(object, data, knots, ...)

## For 'bamlss.frame's.
## S3 method for class 'bamlss.frame'
smooth.construct(object, data = NULL, knots = NULL,
    model = NULL, drop = TRUE, ...)

## S3 method for class 'bamlss.formula'
smooth.construct(object, data = NULL, knots = NULL,
    model = NULL, drop = TRUE, ...)

## S3 method for class 'bamlss.terms'
smooth.construct(object, data = NULL, knots = NULL,
    model = NULL, drop = TRUE, ...)
```

### **Arguments**

object	Either a smooth specification object, or object of class "bamlss", "bamlss.frame", "bamlss.formula" or "bamlss.terms". For smooth specification objects, see function smooth.construct.
data	A data frame or list, see also see function smooth.construct.
knots	See function smooth.construct.

model	Character, specifies for which model parameter the smooth constructs should be created.
drop	If there is only one model parameter the returned named list is simplified.
	Arguments passed to the smooth term constructor functions.

#### Value

For smooth specification objects see function see smooth.construct. For objects of class "bamlss.frame" or "bamlss" the list of smooth constructs, see function bamlss.frame for more details.

## See Also

```
smooth. construct. kr. smooth. spec \\ \textit{Kriging Smooth Constructor}
```

# Description

This smooth constructor implements a kriging based model term.

# Usage

```
## S3 method for class 'kr.smooth.spec'
smooth.construct(object, data, knots, ...)
## S3 method for class 'kriging.smooth'
Predict.matrix(object, data)
```

## **Arguments**

```
object, data, knots
See smooth.construct.
... Currently not used.
```

### **Details**

This smooth constructor implements univariate and bivariate Kriging terms. The basis functions are based on the Matern covariance function. For finding knots, a space filling algorithm is used, see cover.design.

## Value

A smooth specification object, see also smooth.construct.

    sigma ~ s(x1) + s(x2) + s(x3)
)

## Estimate model with MCMC.
b <- bamlss(f, data = d)

## Run the check, note that all variables
## for sigma should have no effect.
smooth_check(b)

## End(Not run)</pre>
```

stabsel 135

# Description

Performs stability selection based on gradient boosting.

## Usage

```
stabsel(formula, data, family = "gaussian",
   q, maxit, B = 100, thr = .9, fraction = 0.5, seed = NULL, ...)
## Plot selection frequencies.
## S3 method for class 'stabsel'
plot(x, show = NULL,
   pal = function(n) gray.colors(n, start = 0.9, end = 0.3), ...)
```

## **Arguments**

formula	A formula or extended formula.
data	A data.frame.
family	A bamlss.family object.
q	An integer specifying how many terms to select in each boosting run.
maxit	An integer specifying the maximum number of boosting iterations. See opt_boost. Either choose q or maxit as hyper-parameter for regularization.
В	An integer. The boosting is run B times.
thr	Cut-off threshold of relative frequencies (between 0 and 1) for selection.
fraction	Numeric between 0 and 1. The fraction of data to be used in each boosting run.
seed	A seed to be set before the stability selection.
x	A object of class stabsel.
show	Number of terms to be shown.
pal	Color palette for different model terms.
	Not used yet in stabsel.

### **Details**

stabsel performs stability selection based on gradient boosting (opt\_boost): The boosting algorithm is run B times on a randomly drawn fraction of the data. Each boosting run is stopped either when q terms have been selected, or when maxit iterations have been performed, i.e. either q or maxit can be used to tune the regularization of the boosting. After the boosting the relative selection frequencies are evaluated. Terms with a relative selection frequency larger then thr are suggested for a final regression model.

136 summary.bamlss

If neither q nor maxit has been specified, q will be set to the square root of the number of columns in data.

Gradient boosting does not depend on random numbers. Thus, the individual boosting runs differ only in the subset of data which is used.

#### Value

A object of class stabsel.

#### Author(s)

Thorsten Simon

## **Examples**

```
## Not run: ## Simulate some data.
set.seed(111)
d <- GAMart()</pre>
n <- nrow(d)</pre>
## Add some noise variables.
for(i in 4:9)
  d[[paste0("x",i)]] \leftarrow rnorm(n)
f <- paste0("~ ", paste("s(x", 1:9, ")", collapse = "+", sep = "")) f <- paste(f, "+ te(lon,lat)")
f <- as.formula(f)</pre>
f \leftarrow list(update(f, num \sim .), f)
## Run stability selection.
sel \leftarrow stabsel(f, data = d, q = 6, B = 10)
plot(sel)
## Estimate selected model.
nf <- formula(sel)</pre>
b <- bamlss(nf, data = d)</pre>
plot(b)
## End(Not run)
```

summary.bamlss

Summary for BAMLSS

# Description

The function takes an object of class "bamlss" and produces summaries of optimizer and sampler function outputs.

summary.bamlss 137

### Usage

```
## S3 method for class 'bamlss'
summary(object, model = NULL,
   FUN = NULL, parameters = TRUE, ...)
## S3 method for class 'summary.bamlss'
print(x, digits = max(3, getOption("digits") - 3), ...)
```

#### Arguments

object An object of class "bamlss".

x An oject of class "summary.bamlss".

model Character or integer, specifies the model for which a summary should be com-

puted.

FUN Function that should be applied on samples, see also function coef.bamlss.

parameters If an optimizer function is applied within the bamlss call, should the values of

the estimated parameters be part of the summary?

digits Controls number of digits printed in output.

... Other arguments.

#### **Details**

If the fitted model contains samples, summaries according to the supplied function can be computed, e.g., different quantiles of samples. See also function coef.bamlss that extracts the coefficient summaries.

If an optimizer function was used within the bamlss call, estimated parameters will be included per default into the summary.

Note that summaries not based on samples can be user defined, e.g., as returned from function samplestats or the return values of optimizer function, e.g., see function opt\_bfit.

## Value

summary. bamlss produces the following summary:

call The initial bamlss call.

family The family that is used for modeling.

formula The model formula.

model.matrix Summary of parameteric terms.

smooth.construct

Summary of smooth terms.

model.stats Other model statistics, e.g., as returned from optimizer functions and/or pro-

duces by function samplestats.

### **Examples**

```
## Not run: ## Generate some data.
d <- GAMart()

## Model formula.
f <- list(
   num ~ s(x1) + s(x2),
   sigma ~ s(x3) + te(lon,lat)
)

## Estimate model.
b <- bamlss(f, data = d)

## Print the summary.
print(summary(b))

## End(Not run)</pre>
```

Surv2

Create a Survival Object for Joint Models

## **Description**

This function is only a slight extension of Surv for joint models.

### Usage

```
Surv2(..., obs = NULL)
```

## **Arguments**

Arguments passed to function Surv.obsThe observed longitudinal response.

## Value

An object of class "Surv2" and "matrix".

## See Also

```
opt_JM, sam_JM, bamlss
```

```
## Surv2(time, event, obs = y)
## See the examples of opt_JM() and sam_JM()!
```

surv\_transform 139

	surv_transform	Survival Model Transformer Function	
--	----------------	-------------------------------------	--

# Description

This function takes a bamlss.frame and computes design matrices of model terms based on a time grid for time-dependent structured additive predictors in a survival context. Note that this transformer function is usually used internally by function bamlss and is the default transformer function using the cox\_bamlss family object.

The time grid design matrices can be used to construct the full structured additive predictor for each time point. This way it is possible to solve the integrals that are part of, e.g., a Newton-Raphson updating scheme, numerically.

See the example section on how to extract the time grid design matrices.

## Usage

```
surv_transform(x, y, data, family,
  subdivisions = 100, timedependent = "lambda",
  timevar = NULL, idvar = NULL, is.cox = FALSE,
  alpha = 0.1, ...)
```

### **Arguments**

X	The x list, as returned from function bamlss.frame and transformed by function surv_transform, holding all model matrices and other information that is used for fitting the model.
У	The model response, as returned from function bamlss.frame.
data	The data frame that should be used for setting up all matrices.
family	A <b>bamlss</b> family object, see family.bamlss. In this case this is the cox_bamlss family object.
subdivisions	How many time points should be created for each individual.
timedependent	A character vector specifying the names of parameters in x that are time-dependent. Time grid design matrices are only computed for these parameters.
timevar	A character specifying the name of the survival time variable in the data set.
idvar	Depending on the type of data set, this is the name of the variable specifying identifier of individuals.
is.cox	Should the bamlss.frame be set up for a Cox type survival model.
alpha	A value for the intercept of a parameter names alpha. Typically the association parameter of a longitudinal and survival process in a joint model.
	Arguments passed to function bamlss.engine.setup.

## Value

A bamlss.frame including the time grid design matrices.

140 terms.bamlss

terms.bamlss 141

## **Description**

Extract terms.objects for BAMLSS.

## Usage

```
## S3 method for class 'bamlss'
terms(x, specials = NULL, data = NULL,
    model = NULL, pterms = TRUE, sterms = TRUE,
    drop = TRUE, ...)

## S3 method for class 'bamlss.frame'
terms(x, specials = NULL, data = NULL,
    model = NULL, pterms = TRUE, sterms = TRUE,
    drop = TRUE, ...)

## S3 method for class 'bamlss.formula'
terms(x, specials = NULL, data = NULL,
    model = NULL, pterms = TRUE, sterms = TRUE,
    drop = TRUE, ...)
```

## **Arguments**

X	An link{bamlss}, bamlss.frame or bamlss.formula object.
specials	See terms.object.
data	Data passed to terms.formula.
model	Character or integer, specifies the model for which terms should be returned.
pterms	Should parametric terms be part of the object?
sterms	Should smooth terms be part of the object?
drop	If terms for only one model are returned, the list structure is dropped.
	Arguments passed to bamlss.formula.

## Value

Object of class "bamlss.terms", a list of terms.objects, depending on the structure of the bamlss.formula object.

trans\_AR1

AR1 Transformer Function

# Description

The transformer function takes a bamlss.frame object and transforms the response and the design matrices to account for lag 1 autocorrelation. The method is also known as Prais-Winsten estimation.

## Usage

```
trans_AR1(rho = 0.1)
AR1(rho = 0.1)
```

## **Arguments**

rho

Specifies the correlation parameter at lag 1.

### Value

A transformer function which can be used in the bamlss call.

144 WAIC

## **Description**

This function creates a data set based on the volcano data by adding normal errors to the topographic information.

## Usage

```
Volcano(sd = 0.3)
```

### **Arguments**

sd

The standard deviation of the normal errors.

## Value

A data frame with coordinates and noisy elevation.

### See Also

volcano

## **Examples**

```
d <- Volcano()
head(d)

## Not run: b <- bamlss(y ~ te(lon,lat,k=10), data = d)
plot(b, theta = -130)

## End(Not run)</pre>
```

WAIC

Watanabe-Akaike Information Criterion (WAIC)

## Description

Function returning the Watanabe-Akaike Information Criterion (WAIC) of a fitted model object.

# Usage

```
WAIC(object, ..., newdata = NULL)
```

### **Arguments**

object A fitted model object which contains MCMC samples.

... Optionally more fitted model objects.

newdata Optionally, use new data for computing the WAIC.

WAIC 145

## Value

A data frame containing the WAIC and estimated number of parameters.
