Package 'dtts'

October 13, 2022

Type Package

Title 'data.table' Time-Series

Version 0.1.0

Date 2022-03-06

Author Dirk Eddelbuettel and Leonardo Silvestri

Maintainer Dirk Eddelbuettel <edd@debian.org>

Description High-frequency time-series support via 'nanotime' and 'data.table'.

License GPL (>= 2)

Imports nanotime, data.table, methods, bit64, Rcpp (>= 0.11.5),
RcppCCTZ (>= 0.2.0)

Suggests tinytest

LinkingTo Rcpp, RcppCCTZ, RcppDate, nanotime

BugReports https://github.com/eddelbuettel/dtts/issues

RoxygenNote 7.1.2

Encoding UTF-8

NeedsCompilation yes

align	*Align a* data.table *onto a* nanotime *vector*

Description

align returns the subset of data.table x that aligns on the temporal vector y

Usage

```
align(x, y, start, end, ...)

## S4 method for signature 'data.table,nanotime,nanoduration,nanoduration'
align(
  x,
  y,
  start = as.nanoduration(0),
  end = as.nanoduration(0),
  sopen = FALSE,
  eopen = TRUE,
  func = NULL
)

## S4 method for signature 'data.table,nanotime,missing,missing'
align(
  x,
  y,
  start = as.nanoduration(0),
  end = as.nanoduration(0),
  sopen = FALSE,
  eopen = TRUE,
  func = NULL
)

## S4 method for signature 'data.table,nanotime,nanoduration,missing'
align(
  x,
  y,
  start = as.nanoduration(0),
  end = as.nanoduration(0),
  sopen = FALSE,
  eopen = TRUE,
  func = NULL
)

## S4 method for signature 'data.table,nanotime,missing,nanoduration'
align(
  x,
```

```
  y,
  start = as.nanoduration(0),
  end = as.nanoduration(0),
  sopen = FALSE,
  eopen = TRUE,
  func = NULL
)

## S4 method for signature 'data.table,nanotime,nanoperiod,nanoperiod'
align(
  x,
  y,
  start = as.nanoperiod(0),
  end = as.nanoperiod(0),
  sopen = FALSE,
  eopen = TRUE,
  tz,
  func = NULL
)

## S4 method for signature 'data.table,nanotime,nanoperiod,missing'
align(
  x,
  y,
  start = as.nanoperiod(0),
  end = as.nanoperiod(0),
  sopen = FALSE,
  eopen = TRUE,
  tz,
  func = NULL
)

## S4 method for signature 'data.table,nanotime,missing,nanoperiod'
align(
  x,
  y,
  start = as.nanoperiod(0),
  end = as.nanoperiod(0),
  sopen = FALSE,
  eopen = TRUE,
  tz,
  func = NULL
)
```

Arguments

x	the data.table time-series to align from
y	the nanotime vector to align to

start	scalar or vector of same length as y of type `integer64`; `start` is added to each element in y and it then defines the starting point of the interval under consideration for the alignment on that element of y
end	scalar or vector of same length as y of type `integer64`; `start` is added to each element in y and it then defines the ending point of the interval under consideration for the alignment on that element of y
...	further arguments passed to or from methods.
sopen	boolean scalar or vector of same lengths as y that indicates if the start of the interval is open or closed. Defaults to FALSE.
eopen	boolean scalar or vector of same lengths as y that indicates if the end of the interval is open or closed. Defaults to TRUE.
func	a function taking one argument and which provides an arbitrary aggregation of its argument; if `NULL` then a function which takes the closest observation is used.
tz	scalar or vector of same length as y of type character. Only used when the type of `start` and end is `nanoperiod`. It defines the time zone for the definition of the interval.

Details

For each element in y, intervals are created around this element with `start` and `end`. All the elements of x that fall within this interval are given as argument to the function `func`. The function `func` show reduce this `data.frame` to one unique row that will be associated with the `nanotime` value in y.

Value

a `data.table` time-series of the same length as y; this is a subset of x with the `nanotime` index of y

Examples

```
## Not run:
y <- nanotime((1:10)*1e9)
x <- data.table(index=nanotime((1:10)*1e9), data=1:10)
align(x, y, as.nanoduration(-1e9), as.nanoduration(1e9), colMeans)

## End(Not run)
```

---

align.idx   *Get the index of the alignment of one vector onto another*

Description

`align.idx` returns the index of the alignment of x on y

Usage

```
align.idx(x, y, start, end, ...)

## S4 method for signature 'nanotime,nanotime,nanoduration,nanoduration'
align.idx(
  x,
  y,
  start,
  end,
  sopen = FALSE,
  eopen = TRUE,
  bypass_x_check = FALSE,
  bypass_y_check = FALSE
)

## S4 method for signature 'nanotime,nanotime,missing,missing'
align.idx(
  x,
  y,
  start,
  end,
  sopen = FALSE,
  eopen = TRUE,
  bypass_x_check = FALSE,
  bypass_y_check = FALSE
)

## S4 method for signature 'nanotime,nanotime,missing,nanoduration'
align.idx(
  x,
  y,
  start,
  end,
  sopen = FALSE,
  eopen = TRUE,
  bypass_x_check = FALSE,
  bypass_y_check = FALSE
)

## S4 method for signature 'nanotime,nanotime,nanoduration,missing'
align.idx(
  x,
  y,
  start,
  end,
  sopen = FALSE,
  eopen = TRUE,
  bypass_x_check = FALSE,
```

```
    bypass_y_check = FALSE
)

## S4 method for signature 'nanotime,nanotime,nanoperiod,nanoperiod'
align.idx(
  x,
  y,
  start = as.nanoperiod(0),
  end = as.nanoperiod(0),
  sopen = FALSE,
  eopen = TRUE,
  tz,
  bypass_x_check = FALSE,
  bypass_y_check = FALSE
)

## S4 method for signature 'nanotime,nanotime,missing,nanoperiod'
align.idx(
  x,
  y,
  start = as.nanoperiod(0),
  end = as.nanoperiod(0),
  sopen = FALSE,
  eopen = TRUE,
  tz,
  bypass_x_check = FALSE,
  bypass_y_check = FALSE
)

## S4 method for signature 'nanotime,nanotime,nanoperiod,missing'
align.idx(
  x,
  y,
  start = as.nanoperiod(0),
  end = as.nanoperiod(0),
  sopen = FALSE,
  eopen = TRUE,
  tz,
  bypass_x_check = FALSE,
  bypass_y_check = FALSE
)
```

Arguments

x	the nanotime vector to align from
y	the nanotime vector to align to
start	scalar or vector of same length as y of type nanoduration or nanoperiod; start is added to each element in y and it then defines the starting point of the

	interval under consideration for the alignment on that element of y
end	scalar or vector of same length as y of type nanoduration or nanoperiod; start is added to each element in y and it then defines the ending point of the interval under consideration for the alignment on that element of y
...	further arguments passed to or from methods.
sopen	boolean scalar or vector of same lengths as y that indicates if the start of the interval is open or closed. Defaults to FALSE.
eopen	boolean scalar or vector of same lengths as y that indicates if the end of the interval is open or closed. Defaults to TRUE.
bypass_x_check	logical indicating if the sorting of x should be bypassed. This can provide a marginal speedup, but should be used carefully.
bypass_y_check	logical indicating if the sorting of y should be bypassed. This can provide a marginal speedup, but should be used carefully.
tz	scalar or vector of same length as y of type character. Only used when the type of start and end is nanoperiod. It defines the time zone for the definition of the interval.

Details

In order to perform the alignment, intervals are created around each elements in y using start and end. For each such interval, the closest element in x is chosen. If no element in x falls in the interval, then NaN is returned.

When only x and y are specified, the default is to close the intervals so that the alignment simply picks up equal points. Note that it is possible to specify meaningless intervals, for instance with a start that is beyond end. In this case, the alignment will simply return NA for each element in y. In principle, the start and end are chosen to define an interval is the past, or around the points in y, but if they are both positive, they can define intervals in the future.

Value

a vector of indices of the same length as y; this vector indexes into x and represent the closest point of x that is in the interval defined around each point in y

Examples

```
## Not run:
align.idx(nanotime(c(10:14, 17:19)), nanotime(11:20))
## [1]  2  3  4  5 NA NA  6  7  8 NA

## End(Not run)
```

`frequency,data.table-method`

Return the number of observations per interval

Description

`frequency` returns the number of observations in `data.table` x for each interval specified by by.

Usage

```
## S4 method for signature 'data.table'
frequency(
  x,
  by,
  grid_start,
  grid_end,
  tz,
  ival_start = -by,
  ival_end,
  ival_sopen = FALSE,
  ival_eopen = TRUE
)
```

Arguments

x	the `data.table` time-series for which to calculate the frequency
by	interval specified as a `nanoduration` or `nanoperiod`.
grid_start	scalar `nanotime` defining the start of the grid; by default the first element of x is taken.
grid_end	scalar `nanotime` defining the end of the grid; by default the last element of x is taken.
tz	scalar of type character. Only used when the type of by and end is `nanoperiod`. It defines the time zone for the definition of the interval.
ival_start	scalar of type `nanoduration` or `nanoperiod`; `ival_start` is added to each element of the grid and it then defines the starting point of the interval under consideration for the alignment onto that element. This defaults to -by and most likely does not need to be overriden.
ival_end	scalar of type `nanoduration` or `nanoperiod`; `ival_end` is added to each element of the grid and it then defines the ending point of the interval under consideration for the alignment onto that element. This defaults to 0 and most likely does not need to be overriden.
ival_sopen	boolean scalar that indicates if the start of the interval is open or closed. Defaults to FALSE.
ival_eopen	boolean scalar that indicates if the end of the interval is open or closed. Defaults to TRUE.

Value

a `data.table` time-series with the number of observations in x that fall withing the intervals defined by the grid interval defined by by.

Examples

```
## Not run:
one_second <- as.nanoduration("00:00:01")
one_minute <- 60 * one_second
x <- data.table(index=nanotime((1:100) * one_second), 1)
setkey(x, index)
frequency(x, one_minute)

## End(Not run)
```

---

grid.align	*Align a* data.table *onto a* nanotime *vector grid*

Description

`grid.align` returns the subset of `data.table` x that aligns on the grid defined by by, start and end

Usage

```
grid.align(x, by, ...)

## S4 method for signature 'data.table,nanoduration'
grid.align(
  x,
  by,
  func = NULL,
  grid_start = x[[1]][1] + by,
  grid_end = tail(x[[1]], 1),
  ival_start = -by,
  ival_end = as.nanoduration(0),
  ival_sopen = FALSE,
  ival_eopen = TRUE
)

## S4 method for signature 'data.table,nanoperiod'
grid.align(
  x,
  by,
  func = NULL,
  grid_start = plus(x[[1]][1], by, tz),
  grid_end = tail(x[[1]], 1),
```

```
    ival_start = -by,
    ival_end = as.nanoperiod(0),
    ival_sopen = FALSE,
    ival_eopen = TRUE,
    tz
)
```

Arguments

x	the `data.table` time-series to align from
by	interval specified as a `nanoduration` or `nanoperiod`.
...	further arguments passed to or from methods.
func	a function taking one argument and which provides an arbitrary aggregation of its argument; if `NULL` then a function which takes the closest observation is used.
grid_start	scalar `nanotime` defining the start of the grid; by default the first element of `x` is taken.
grid_end	scalar `nanotime` defining the end of the grid; by default the last element of `x` is taken.
ival_start	scalar of type `nanoduration` or `nanoperiod`; `ival_start` is added to each element of the grid and it then defines the starting point of the interval under consideration for the alignment onto that element.
ival_end	scalar of type `nanoduration` or `nanoperiod`; `ival_end` is added to each element of the grid and it then defines the ending point of the interval under consideration for the alignment onto that element.
ival_sopen	boolean scalar that indicates if the start of the interval is open or closed. Defaults to FALSE.
ival_eopen	boolean scalar that indicates if the end of the interval is open or closed. Defaults to TRUE.
tz	scalar of type character. Only used when the type of `by` and `end` is `nanoperiod`. It defines the time zone for the definition of the interval.

Details

A grid defined by the parameter `by`, `start` and `end` is created. The function then does a standard alignment of `x` onto this grid (see the `align` function)

Value

a `data.table` time-series of the same length as `y` with the aggregations computed by `func`

Examples

```
## Not run:
one_second <- 1e9
x <- data.table(index=nanotime(cumsum(sin(seq(0.001, pi, 0.001)) * one_second)))
x <- x[, V2 := 1:nrow(x)]
setkey(x, index)
```

```
grid.align(x, as.nanoduration("00:01:00"), sum)

## End(Not run)
```

Index
