Depends R (>= 2.10.0), survival, boot, MASS, survC1, doBy

Imports statmod, nlme, shiny, rootSolve, splines

LazyLoad no

Description The following several classes of frailty models using a penalized likelihood estima-
tion on the hazard function but also a parametric estimation can be fit using this R package:
   1) A shared frailty model (with gamma or log-normal frailty distribution) and Cox propor-
tional hazard model. Clustered and recurrent survival times can be studied.
   2) Additive frailty models for proportional hazard models with two correlated random ef-
fects (intercept random effect with random slope).
   3) Nested frailty models for hierarchically clustered data (with 2 levels of clustering) by in-
cluding two iid gamma random effects.
   4) Joint frailty models in the context of the joint modelling for recurrent events with termi-
nal event for clustered data or not. A joint frailty model for two semi-competing risks and clus-
tered data is also proposed.
      5) Joint general frailty models in the context of the joint modelling for recur-
rent events with terminal event data with two independent frailty terms.
      6) Joint Nested frailty models in the context of the joint modelling for recur-
rent events with terminal event, for hierarchically clustered data (with two levels of cluster-
ing) by including two iid gamma random effects.
      7) Multivariate joint frailty models for two types of recurrent events and a terminal event.
      8) Joint models for longitudinal data and a terminal event.
      9) Trivariate joint models for longitudinal data, recurrent events and a terminal event.
      10) Joint frailty models for the validation of surrogate endpoints in multiple random-
ized clinical trials with failure-time endpoints
      with the possibility to use a mediation analysis model.

1

11) Conditional and Marginal two-
part joint models for longitudinal semicontinuous data and a terminal event.
12) Joint frailty-copula models for the validation of surrogate endpoints in multiple random-
ized clinical trials with failure-time endpoints.

13) Generalized shared and joint frailty models for recurrent and terminal events. Propor-
tional hazards (PH), additive hazard (AH), proportional odds (PO) and probit models are avail-
able in a fully parametric framework. For PH and AH models, it is possible to consider type-
varying coefficients and flexible semiparametric hazard function.

Prediction values are available (for a terminal event or for a new recurrent event). Left-
truncated (not for Joint model), right-censored data, interval-censored data (only for Cox propor-
tional hazard and shared frailty model) and strata are allowed. In each model, the random ef-
fects have the gamma or normal distribution. Now, you can also consider time-varying covari-
ates effects in Cox, shared and joint frailty models (1-5). The package includes concor-
dance measures for Cox proportional hazards models and for shared frailty models.

Moreover, the package can be used with its shiny application, in a local mode or by fol-
lowing the link below.

frailtypack-package   *General Frailty models: shared, joint and nested frailty models with*
                             prediction; Evaluation of Failure-Time Surrogate Endpoints

---

Description

Frailtypack fits several classes of frailty models using a penalized likelihood estimation on the
hazard function but also a parametric estimation. 1) A shared frailty model and Cox proportional
hazard model. Clustered and recurrent survival times can be studied. 2) Additive frailty models
for proportional hazard models with two correlated random effects (intercept random effect with
random slope). 3) Nested frailty models for hierarchically clustered data (with 2 levels of clustering)
by including two iid gamma random effects. 4) Joint frailty models in the context of joint modelling
for recurrent events with terminal event for clustered data or not. A joint frailty model for two semi-
competing risks for clustered data is also proposed. 5) Joint General frailty models in the context
of a joint modelling for recurrent events with terminal event data with two independent frailty
terms. 6) Joint Nested frailty models in the context of joint modelling for recurrent events with
terminal event, for hierarchically clustered data (with two levels of clustering) by including two iid
gamma random effects. 7) Multivariate joint frailty models for two types of recurrent events and
a terminal event. 8) Joint models for longitudinal data and a terminal event. 9) Trivariate joint
models for longitudinal data, recurrent events and a terminal event. Prediction values are available.
Left truncated (not for the joint models), right-censored data, interval-censored data (only for Cox
proportional hazard and shared frailty model) and strata are allowed. In each model, the random
effects have the gamma or normal distribution. Now, you can also consider time-varying effect

covariates in Cox, shared and joint frailty models. The package includes concordance measures for Cox proportional hazards models and for shared frailty models. 10) Joint frailty models for the validation of surrogate endpoints in multiple randomized clinical trials with failure-time endpoints. This model includes a shared individual-level random effect, a shared trial random-effct associated with the hazard risks and a correlated random effects-by-trial interaction.

additivePenal	*Fit an Additive Frailty model using a semiparametric penalized likeli-hood estimation or a parametric estimation*

Description

Fit an additive frailty model using a semiparametric penalized likelihood estimation or a parametric estimation. The main issue in a meta-analysis study is how to take into account the heterogeneity between trials and between the treatment effects across trials. Additive models are proportional hazard model with two correlated random trial effects that act either multiplicatively on the hazard function or in interaction with the treatment, which allows studying for instance meta-analysis or multicentric datasets. Right-censored data are allowed, but not the left-truncated data. A stratified analysis is possible (maximum number of strata = 2). This approach is different from the shared frailty models.

In an additive model, the hazard function for the jth subject in the ith trial with random trial effect u_i as well as the random treatment-by-trial interaction v_i is:

$$\begin{cases} \lambda_{ij}(t|u_i,v_i) = \lambda_0(t)exp(u_i + v_i X_{ij1} + \sum_{k=1}^{p} \beta_k X_{ijk}) \\ \mathbf{cov}(u_i,v_i) = \rho\boldsymbol{\sigma\tau} \\ u_i \sim \boldsymbol{\mathcal{N}}(0,\boldsymbol{\sigma^2}), v_i \sim \boldsymbol{\mathcal{N}}(0,\boldsymbol{\tau^2}) \end{cases}$$

where $\lambda_0(t)$ is the baseline hazard function, β_k the fixed effect associated to the covariate X_{ijk} (k=1,..,p), β_1 is the treatment effect and X_{ij1} the treatment variable. ρ is the corresponding correlation coefficient for the two frailty terms.

Usage

```
additivePenal(formula, data, correlation = FALSE, recurrentAG =
FALSE, cross.validation = FALSE, n.knots, kappa, maxit = 350, hazard =
"Splines", nb.int, LIMparam = 1e-4, LIMlogl = 1e-4, LIMderiv = 1e-3,
print.times = TRUE)
```

Arguments

formula
a formula object, with the response on the left of a $\sim$ operator, and the terms on the right. The response must be a survival object as returned by the 'Surv' function like in survival package. The slope() function is required. Interactions are possible using * or :.

data
a 'data.frame' with the variables used in 'formula'.

correlation
Logical value. Are the random effects correlated? If so, the correlation coefficient is estimated. The default is FALSE.

recurrentAG
Always FALSE for additive models (left-truncated data are not allowed).

cross.validation
Logical value. Is cross validation procedure used for estimating smoothing parameter in the penalized likelihood estimation? If so a search of the smoothing parameter using cross validation is done, with kappa as the seed. The cross validation is not implemented for two strata. The default is FALSE.

n.knots
integer giving the number of knots to use. Value required in the penalized likelihood estimation. It corresponds to the (n.knots+2) splines functions for the approximation of the hazard or the survival functions. Number of knots must be between 4 and 20. (See Note)

kappa
positive smoothing parameter in the penalized likelihood estimation. In a stratified additive model, this argument must be a vector with kappas for both strata. The coefficient kappa of the integral of the squared second derivative of hazard function in the fit. To obtain an initial value for kappa, a solution is to fit the corresponding shared frailty model using cross validation (see cross.validation). We advise the user to identify several possible tuning parameters, note their defaults and look at the sensitivity of the results to varying them. Value required. (See Note)

maxit
maximum number of iterations for the Marquardtt algorithm. Default is 350

hazard
Type of hazard functions: "Splines" for semiparametric hazard functions with the penalized likelihood estimation, "Piecewise-per" for piecewise constant hazards functions using percentile, "Piecewise-equi" for piecewise constant hazard functions using equidistant intervals, "Weibull" for parametric Weibull functions. Default is "Splines".

nb.int
Number of intervals (between 1 and 20) for the parametric hazard functions ("Piecewise-per", "Piecewise-equi").

LIMparam
Convergence threshold of the Marquardt algorithm for the parameters (see Details), 10^{-4} by default.

LIMlogl
Convergence threshold of the Marquardt algorithm for the log-likelihood (see Details), 10^{-4} by default.

| LIMderiv | Convergence threshold of the Marquardt algorithm for the gradient (see Details), 10^{-3} by default. |
| print.times | a logical parameter to print iteration process. Default is TRUE. |

Details

The estimated parameter are obtained by maximizing the penalized log-likelihood or by a simple log-likelihood (in the parametric case) using the robust Marquardtt algorithm (Marquardtt,1963). The parameters are initialized with values obtained with Cox proportional hazard model. The iterations are stopped when the difference between two consecutive loglikelhoods was small ($< 10^{-4}$), the estimated coefficients were stable (consecutive values ($< 10^{-4}$), and the gradient small enough ($< 10^{-3}$). To be sure of having a positive function at all stages of the algorithm, the spline coefficients were reparametrized to be positive at each stage. The variance space of the two random effects is reduced, so the variances are positive, and the correlation coefficient values are constrained to be between -1 and 1. The marginal log-likelihood depends on integrations that are approximated by using the Laplace integration technique with a first order approximation. The smoothing parameter can be fixed or estimated by maximizing likelihood cross-validation criterion. The usual squared Wald statistic was modified to a mixture of two χ^2 distribution to get significance test for the variance of the random effects.

INITIAL VALUES

The splines and the regression coefficients are initialized to 0.1. An adjusted Cox model is fitted, it provides new initial values for the splines coefficients and the regression coefficients. The variances of the frailties are initialized to 0.1. Then an additive frailty model with independent frailties is fitted. At last, an additive frailty model with correlated frailties is fitted.

Value

An additive model or more generally an object of class 'additivePenal'. Methods defined for 'additivePenal' objects are provided for print, plot and summary.

b	sequence of the corresponding estimation of the splines coefficients, the random effects variances and the regression coefficients.
call	The code used for fitting the model.
coef	the regression coefficients.
cov	covariance between the two frailty terms ($\boldsymbol{cov}(u_i, v_i)$)
cross.Val	Logical value. Is cross validation procedure used for estimating the smoothing parameters in the penalized likelihood estimation?
correlation	Logical value. Are the random effects correlated?
DoF	degrees of freedom associated with the "kappa".
formula	the formula part of the code used for the model.
groups	the maximum number of groups used in the fit.
kappa	A vector with the smoothing parameters in the penalized likelihood estimation corresponding to each baseline function as components.
loglikPenal	the complete marginal penalized log-likelihood in the semiparametric case.
loglik	the marginal log-likelihood in the parametric case.

n	the number of observations used in the fit.
n.events	the number of events observed in the fit.
n.iter	number of iterations needed to converge.
n.knots	number of knots for estimating the baseline functions.
n.strat	number of stratum.
rho	the corresponding correlation coefficient for the two frailty terms.
sigma2	Variance for the random intercept (the random effect associated to the baseline hazard functions).
tau2	Variance for the random slope (the random effect associated to the treatment effect across trials).
varH	the variance matrix of all parameters before positivity constraint transformation (Sigma2, Tau2, the regression coefficients and the spline coefficients). Then after, the delta method is needed to obtain the estimated variance parameters.
varHIH	the robust estimation of the variance matrix of all parameters (Sigma2, Tau2, the regression coefficients and the spline coefficients).
varSigma2	The variance of the estimates of "sigma2".
varTau2	The variance of the estimates of "tau2".
varcov	Variance of the estimates of "cov".
x	matrix of times where both survival and hazard functions are estimated. By default seq(0,max(time),length=99), where time is the vector of survival times.
lam	array (dim=3) of hazard estimates and confidence bands.
surv	array (dim=3) of baseline survival estimates and confidence bands.
median	The value of the median survival and its confidence bands. If there are two stratas or more, the first value corresponds to the value for the first strata, etc.
type.of.hazard	Type of hazard functions (0:"Splines", "1:Piecewise", "2:Weibull").
type.of.Piecewise	
	Type of Piecewise hazard functions (1:"percentile", 0:"equidistant").
nbintervR	Number of intervals (between 1 and 20) for the parametric hazard functions ("Piecewise-per", "Piecewise-equi").
npar	number of parameters.
nvar	number of explanatory variables.
noVar	indicator of explanatory variable.
LCV	the approximated likelihood cross-validation criterion in the semiparametric case (with H minus the converged Hessian matrix, and l(.) the full log-likelihood).

$$LCV = \frac{1}{n}(trace(H_{pl}^{-1}H) - l(.))$$

AIC	the Akaike information Criterion for the parametric case.

$$AIC = \frac{1}{n}(np - l(.))$$

n.knots.temp	initial value for the number of knots.
shape.weib	shape parameter for the Weibull hazard function.
scale.weib	scale parameter for the Weibull hazard function.
martingale.res	martingale residuals for each cluster.
frailty.pred	empirical Bayes prediction of the first frailty term.
frailty.pred2	empirical Bayes prediction of the second frailty term.
linear.pred	linear predictor: uses simply "Beta'X + u_i + v_i * X_1" in the additive Frailty models.
global_chisq	a vector with the values of each multivariate Wald test.
dof_chisq	a vector with the degree of freedom for each multivariate Wald test.
global_chisq.test	
	a binary variable equals to 0 when no multivariate Wald is given, 1 otherwise.
p.global_chisq	a vector with the p_values for each global multivariate Wald test.
names.factor	Names of the "as.factor" variables.
Xlevels	vector of the values that factor might have taken.
contrasts	type of contrast for factor variable.
beta_p.value	p-values of the Wald test for the estimated regression coefficients.

Note

"kappa" and "n.knots" are the arguments that the user have to change if the fitted model does not converge. "n.knots" takes integer values between 4 and 20. But with n.knots=20, the model would take a long time to converge. So, usually, begin first with n.knots=7, and increase it step by step until it converges. "kappa" only takes positive values. So, choose a value for kappa (for instance 10000), and if it does not converge, multiply or divide this value by 10 or 5 until it converges.

bcos   *Breast Cosmesis Data*

Description

The often used data set for interval-censored data, described and given in full in Finkelstein and Wolfe (1985). It involves 94 breast cancer patients who were randomized to either radiation therapy with chemotherapy or radiation therapy alone. The outcome is time until the onset of breast retraction which is interval-censored between the last clinic visit before the event was observed and the first visit when the event was observed. Patients without breast retraction were right-censored.

Usage

```
data(bcos)
```

Format

A data frame with 94 observations and 3 variables:

left left end point of the breast retraction interval

right right end point of the breast retraction interval

treatment type of treatment received

Source

Finkelstein, D.M. and Wolfe, R.A. (1985). A semiparametric model for regression analysis of interval-censored failure time data. *Biometrics* **41**, 731-740.

---

cluster | *Identify clusters*

Description

This is a special function used in the context of the models for grouped data. It identifies correlated groups of observations defined by using 'cluster' function, and is used of 'frailtyPenal' formula for fitting univariate and joint models.

Usage

```
cluster(x)
```

Arguments

x   A character, factor, or numeric variable which is supposed to indicate the variable group

Value

x   A variable identified as a cluster

Cmeasures	*Concordance measures in shared frailty and Cox proportional hazard models*

Description

Compute concordance probability estimation for Cox proportional hazard or shared frailty models in case of grouped data (Mauguen et al. 2012). Concordance is given at different levels of comparison, taking into account the cluster membership: between-groups, within-groups and an overall measure, being a weighted average of the previous two. Can also compute the c-index (Harrell et al. 1996) at these three levels. It is possible to exclude tied pairs from concordance estimation (otherwise, account for 1/2).

Usage

```
Cmeasures(fitc, ties = 1, marginal = 0, cindex = 0, Nboot = 0, tau = 0,
data.val)
```

Arguments

fitc	A frailtyPenal object, for a shared frailty model. If the fit is a Cox model, no clustering membership is taken into account and only marginal concordance probability estimation is provided. Only an overall measure is given, where all patients are compared two by two. If a counting process formulation is used to performed the fit, with 't.start' and 't.stop', the gap-times (t.stop-t.start) are used in the concordance estimation.
ties	Indicates if the tied pairs on prediction value must be included (ties=1) or excluded (ties=0) from the concordance estimation. Default is ties=1. When included, tied pairs account for 1/2 in the concordance.
marginal	Indicates if the concordance based on marginal predictions must be given (marginal=1) in addition to conditional ones or not (marginal=0). Marginal predictions do not include the frailty estimation in the linear predictor computation: uses "'Beta'X'" instead of "Beta'X + log z_i". Default is marginal=0.
cindex	Indicates if the c-index (Harrell et al. 1996) must be computed (cindex=1) in addition to the concordance probability estimation or not (cindex=0). C-index is also given at the three comparison levels (between, within and overall). Default is cindex=0.
Nboot	Number of bootstrap resamplings to compute standard-error of the concordances measures, as well as a percentile 95% confidence interval. Nboot=0 indicates no bootstrap procedure. Maximum admitted is 1000. Minimum admitted is 2. Default is 0. Resampling is done at the group level. If Cox model is used, resampling is done at individual level.
tau	Time used to limit the interval on which the concordance is estimated. Note that the survival function for the underlying censoring time distribution needs to be positive at tau. If tau=0, the maximum of the observed event times is used. Default is tau=0.

data.val   A dataframe. It is possible to specify a different dataset than the one used in the model input in the argument 'fitc'. This new dataset will be a validation population and the function will compute new concordance measures from the parameters estimated on the development population. In this case for conditional measures, the frailties are a posteriori predicted. The two datasets must have the same covariates with the same coding without missing data.

Value

call   The shared frailty model evaluated.

Frailty   Logical value. Was model with frailties fitted.

frequencies   Numbers of patients, events and groups used to fit the model.

Npairs   Number of pairs of subjects, between-groups, within-groups and over all the population. If cindex=1, number of comparable (useable) pairs also available.

Nboot   Number of bootstrap resamplings required.

ties   A binary, indicating if the tied pairs on prediction were used to compute the concordance.

CPEcond   Values of Gonen & Heller's measure (conditional). If Nboot>0, give SE, the standard-error of the parameters evaluated by bootstrap, IC.low and IC.high, the lower and upper bounds of the percentile confidence interval evaluated by bootstrap (2.5% and 97.5% percentiles).

Cunocond   Values of Uno's measure (conditional). If Nboot>0, give SE, the standard-error of the parameters evaluated by bootstrap, IC.low and IC.high, the lower and upper bounds of the percentile confidence interval evaluated by bootstrap (2.5% and 97.5% percentiles).

marginal   A binary, indicating if the marginal values were computed.

CPEmarg   Values of Gonen & Heller's measure (marginal), if marginal=1. If Nboot>0, give SE, the standard-error of the parameters evaluated by bootstrap, IC.low and IC.high, the lower and upper bounds of the percentile confidence interval evaluated by bootstrap (2.5% and 97.5% percentiles).

Cunomarg   Values of Uno's measure (marginal), if marginal=1. If Nboot>0, give SE, the standard-error of the parameters evaluated by bootstrap, IC.low and IC.high, the lower and upper bounds of the percentile confidence interval evaluated by bootstrap (2.5% and 97.5% percentiles).

cindex   A binary, indicating if the c-indexes were computed.

cindexcond   Values of the C-index of Harrell (conditional). If Nboot>0, give SE, the standard-error of the parameters evaluated by bootstrap, IC.low and IC.high, the lower and upper bounds of the percentile confidence interval evaluated by bootstrap (2.5% and 97.5% percentiles).

cindexmarg   Values of the C-index of Harrell (marginal), if marginal=1. If Nboot>0, give SE, the standard-error of the parameters evaluated by bootstrap, IC.low and IC.high, the lower and upper bounds of the percentile confidence interval evaluated by bootstrap (2.5% and 97.5% percentiles).

colorectal	*Follow-up of metastatic colorectal cancer patients: times of new lesions appearance and death*

Description

Randomly chosen 150 patients from the follow-up of the FFCD 2000-05 multicenter phase III clinical trial originally including 410 patients with metastatic colorectal cancer randomized into two therapeutic strategies: combination and sequential. The dataset contains times of observed appearances of new lesions censored by a terminal event (death or right-censoring) with baseline characteristics (treatment arm, age, WHO performance status and previous resection).

Usage

```
data(colorectal)
```

Format

This data frame contains the following columns:

id identification of each subject. Repeated for each recurrence

time0 start of interval (0 or previous recurrence time)

time1 recurrence or censoring time

new.lesions Appearance of new lesions status. 0: censsored or no event, 1: new lesions

treatment To which treatment arm a patient was allocated? 1: sequential (S); 2: combination (C)

age Age at baseline: 1: <50 years, 2: 50-69 years, 3: >69 years

who.PS WHO performance status at baseline: 1: status 0, 2: status 1, 3: status 2

prev.resection Previous resection of the primate tumor? 0: No, 1: Yes

state death indicator. 0: alive, 1: dead

gap.time interocurrence time or censoring time

Note

We thank the Federation Francophone de Cancerologie Digestive and Gustave Roussy for sharing the data of the FFCD 2000-05 trial supported by an unrestricted Grant from Sanofi.

colorectalLongi	*Follow-up of metastatic colorectal cancer patients : longitudinal measurements of tumor size*

Description

Randomly chosen 150 patients from the follow-up of the FFCD 2000-05 multicenter phase III clinical trial originally including 410 patients with metastatic colorectal cancer randomized into two therapeutic strategies: combination and sequential. The dataset contains measurements of tumor size (left-censored sums of the longest diameters of target lesions; transformed using Box-Cox) with baseline characteristics(treatment arm, age, WHO performance status and previous resection).

Usage

```
data(colorectalLongi)
```

Format

This data frame contains the following columns:

id identification of each subject. Repeated for each recurrence

year time of visit counted in years from baseline

tumor.size Individual longitudinal measurement of transformed (Box-Cox with parameter 0.3) sums of the longest diameters, left-censored due to a detection limit (threshold $s = -3.33$).

treatment To which treatment arm a patient was allocated? 1: sequential (S); 2: combination (C)

age Age at baseline: 1: <50 years, 2: 50-69 years, 3: >69 years

who.PS WHO performance status at baseline: 1: status 0, 2: status 1, 3: status 2

prev.resection Previous resection of the primate tumor? 0: No, 1: Yes

Note

---

dataAdditive   *Simulated data as a gathering of clinical trials databases*

Description

This contains simulated samples of 100 clusters with 100 subjects in each cluster, like a gathering
of clinical trials databases. Two correlated centred gaussian random effects are generated with the
same variance fixed at 0.3 and the covariance at -0.2. The regression coefficient β is fixed at -0.11.
The percentage of right-censored data is around 30 percent which are generated from a uniform
distribution on [1,150]. The baseline hazard function is considered as a simple Weibull.

Usage

```
data(dataAdditive)
```

Format

This data frame contains the following columns:

group identification variable

t1 start of interval (=0, because left-truncated data are not allowed)

t2 end of interval (death or censoring time)

event censoring status (0:alive, 1:death, as acensoring indicator

var1 dichotomous covariate (=0 or 1,as a treatment variable)

var2 dichotomous covariate (=0 or 1,as a treatment variable)

Source

V. Rondeau, S. Michiels, B.Liquet, and J.P. Pignon (2008). Investigating trial and treatment het-
erogeneity in an individual patient data meta-analysis of survival data by mean of the maximum
penalized likelihood approach. *Statistics in Medecine*, **27**, 1894-1910.

---

dataMultiv   *Simulated data for two types of recurrent events and a terminal event*

Description

This contains a simulated sample of of 800 subjects and 1652 observations. This dataset can be
used to illustrate how to fit a joint multivariate frailty model. Two gaussian correlated random
effects were generated with mean 0, variances 0.5 and a correlation coefficient equals to 0.5. The
coefficients α_1 and α_2 were fixed to 1. The three baseline hazard functions followed a Weibull
distribution and right censoring was fixed at 5.

Usage

```
data(dataMultiv)
```

Format

This data frame contains the following columns:

PATIENT identification of patient

obs number of observation for a patient

TIME0 start of interval

TIME1 end of interval (death or censoring time)

INDICREC recurrent of type 1 status (0:no, 1:yes)

INDICMETA recurrent of type 2 status (0:no, 1:yes)

INDICDEATH censoring status (0:alive, 1:death)

v1 dichotomous covariate (0,1)

v2 dichotomous covariate (0,1)

v3 dichotomous covariate (0,1)

TIMEGAP time to event

---

dataNCC	*Simulated data for recurrent events and a terminal event with weigths using nested case-control design*

Description

This contains a simulated sample of of 819 subjects and 1510 observations. This dataset can be used to illustrate how to fit a joint frailty model for data from nested case-control studies.

Usage

```
data(dataNCC)
```

Format

This data frame contains the following columns:

id identification of patient

cov1 dichotomous covariate (0,1)

cov2 dichotomous covariate (0,1)

t.start start of interval

t.stop end of interval (death or censoring time)

gaptime time to event

event recurrent event status (0:no, 1:yes)

deathdays time of terminal event (death or right-censoring)

death censoring status (0:alive, 1:death)

ncc.wts weights for NCC design

---

dataNested   *Simulated data with two levels of grouping*

Description

This contains a simulated sample of 400 observations which allow establishing 20 clusters with 4 subgroups and 5 subjects in each subgroup, in order to obtain two levels of grouping. This data set is useful to illustrate how to fit a nested model. Two independent gamma frailty parameters with a variance fixed at 0.1 for the cluster effect and at 0.5 for the subcluster effect were generated. Independent survival times were generated from a simple Weibull baseline risk function. The percentage of censoring data was around 30 per cent. The right-censoring variables were generated from a uniform distribution on [1,36] and a left-truncating variable was generated with a uniform distribution on [0,10]. Observations were included only if the survival time is greater than the truncated time.

Usage

```
data(dataNested)
```

Format

This data frame contains the following columns:

group group identification variable

subgroup subgroup identification variable

t1 start of interval (0 or truncated time)

t2 end of interval (death or censoring time)

event censoring status (0: alive, 1: death)

cov1 dichotomous covariate (0,1)

cov2 dichotomous covariate (0,1)

Source

dataOvarian   *Advanced Ovarian Cancer dataset*

Description

This dataset combines the data that were collected in four double-blind randomized clinical trials in advanced ovarian cancer. In these trials, the objective was to examine the efficacy of cyclophosphamide plus cisplatin (CP) versus cyclophosphamide plus adriamycin plus cisplatin (CAP) to treat advanced ovarian cancer. The candidate surrogate endpoint **S** is progression-free survival time, defined as the time (in years) from randomization to clinical progression of the disease or death. The true endpoint **T** is survival time, defined as the time (in years) from randomization to death of any cause

Usage

    data(dataOvarian)

Format

This data frame contains the following columns:

patientID The identification number of a patient

trialID The center in which a patient was treated

trt The treatment indicator, coded as 0 = cyclophosphamide plus cisplatin (CP) and 1 = cyclophosphamide plus adriamycin plus cisplatin(CAP)

timeS The candidate surrogate (progression-free survival)

statusS Censoring indicator for for Progression-free survival

timeT The true endpoint (survival time)

statusT Censoring indicator for survival time

Source

Ovarian cancer Meta-Analysis Project (1991). Cyclophosphamide plus cisplatin plus adriamycin versus Cyclophosphamide, doxorubicin, and cisplatin chemotherapy of ovarian carcinoma: A meta-analysis. *Classic Papers and Current Comments*, **3**, 237-234.

Diffepoce   *Difference of Expected Prognostic Observed Cross-Entropy (EPOCE)*
                             estimators and its 95% tracking interval between two joint models.

Description

This function computes the difference of two EPOCE estimates (CVPOL and MPOL) and its 95% tracking interval between two joint models estimated using `frailtyPenal`, `longiPenal` or `trivPenal`. Difference in CVPOL is computed when the EPOCE was previously estimated on the same dataset as used for estimation (using an approximated cross-validation), and difference in MPOL is computed when the EPOCE was previously estimated on an external dataset.

Usage

```
Diffepoce(epoce1, epoce2)
```

Arguments

epoce1   a first object inheriting from class epoce.

epoce2   a second object inheriting from class epoce.

Details

From the EPOCE estimates and the individual contributions to the prognostic observed log-likelihood obtained with epoce function on the same dataset from two different estimated joint models, the difference of CVPOL (or MPOL) and its 95% tracking interval is computed. The 95% tracking interval is : Delta(MPOL) +/- qnorm(0.975)*sqrt(VARIANCE) for an external dataset Delta(CVPOL) +/- qnorm(0.975)*sqrt(VARIANCE) for the dataset used in `frailtyPenal`, `longiPenal` or `trivPenal` where Delta(CVPOL) (or Delta(MPOL)) is the difference of CVPOL (or MPOL) of the two joint models, and VARIANCE is the empirical variance of the difference of individuals contributions to the prognostic observed log-likelihoods of the two joint models.

The estimators of EPOCE from arguments epoce1 and epoce2 must have been computed on the same dataset and with the pred.times.

Value

new.data   a boolean which is FALSE if computation is done on the same data as for esti-
                mation, and TRUE otherwise

pred.times   time or vector of times used in the function

DEPOCE   the difference between the two MPOL or CVPOL for each time

TIinf   lower confidence band for the difference

TIsup   upper confidence band for the difference

epoce | *Estimators of the Expected Prognostic Observed Cross-Entropy (EPOCE) for evaluating predictive accuracy of joint models.*

Description

This function computes estimators of the Expected Prognostic Observed Cross-Entropy (EPOCE) for evaluating the predictive accuracy of joint models using `frailtyPenal`, `longiPenal`, `trivPenal` or `trivPenalNL`. On the same data as used for estimation of the joint model, this function computes both the Mean Prognosis Observed Loss (MPOL) and the Cross-Validated Prognosis Observed Loss (CVPOL), two estimators of EPOCE. The latter corrects the MPOL estimate for over-optimism by approximated cross-validation. On external, this function only computes MPOL.

Usage

```
epoce(fit, pred.times, newdata = NULL, newdata.Longi = NULL)
```

Arguments

`fit`	A jointPenal, longiPenal, trivPenal or trivPenalNL object.
`pred.times`	Time or vector of times to compute epoce.
`newdata`	Optional. In case of joint models obtained with `frailtyPenal`, `trivPenal` or `trivPenalNL`. For models inheriting from `trivPenal` or `trivPenalNL` class, if `newdata` is given, `newdata.Longi` must be given as well. When missing, the data used for estimating the fit are used, and CVPOL and MPOL are computed (internal validation). When `newdata` is specified, only MPOL is computed on this new dataset (external validation). The new dataset and the dataset used in the estimation must have the same covariates with the same coding without missing data.
`newdata.Longi`	Optional. In case of joint models obtained with `longiPenal`, `trivPenal` or `trivPenalNL`. For models inheriting from `longiPenal`, if the `newdata.Longi` is given, `newdata` must be NULL, but for models from `trivPenal` or `trivPenalNL` class, if `newdata.Longi` is given, `newdata` must be provided as well. The two datasets newdata and newdata.Longi must include the information concerning the same patients with the same characteristics and the appropriate data on follow up (recurrences for `newdata` and longitudinal measurements for `newdata.Longi`).

Value

`data`	name of the data used to compute epoce
`new.data`	a boolean which is FALSE if computation is done on the same data as for estimation, and TRUE otherwise
`pred.times`	time or vector of times used in the function
`mpol`	values of MPOL for each pred.times
`cvpol`	values of CVPOL for each pred.times
`IndivContrib`	all the contributions to the log-likelihood for each pred.times
`AtRisk`	number of subject still at risk for each pred.times

event2   *Identify event2 indicator*

Description

This is a special function used in the context of multivariate frailty model with two types of recurrent events and a terminal event (e.g., censoring variable related to both recurrent events). It contains the indicator of the recurrent event of type 2, normally 0=no event, 1=event, and is used on the right hand side of a formula of a 'multivPenal' object. Using event2() in a formula implies that a multivariate frailty model for two types of recurrent events and a terminal event is fitted.

Usage

```
event2(x)
```

Arguments

x   A numeric variable but should be a boolean which equals 1 if the subject has
                experienced an event of type 2 and 0 if not.

Value

x   an indicator for an event of type 2

[multivPenal](#)

| frailtyPenal | *Fit a Shared, Joint or Nested Frailty model* |

Description

Shared Frailty model

Fit a shared gamma or log-normal frailty model using a semiparametric Penalized Likelihood estimation or parametric estimation on the hazard function. Left-truncated, right-censored data, interval-censored data and strata (up to 6 levels) are allowed. It allows to obtain a non-parametric smooth hazard of survival function. This approach is different from the partial penalized likelihood approach of Therneau et al.

The hazard function, conditional on the frailty term ω_i, of a shared gamma frailty model for the jth subject in the ith group:

$$\lambda_{ij}(t|\omega_i) = \lambda_0(t)\omega_i \exp(\boldsymbol{\beta}' \boldsymbol{Z_{ij}})$$

$$\omega_i \sim \Gamma\left(\frac{1}{\theta}, \frac{1}{\theta}\right) \quad \boldsymbol{E}(\omega_i) = 1 \quad \boldsymbol{Var}(\omega_i) = \theta$$

where $\lambda_0(t)$ is the baseline hazard function, $\boldsymbol{\beta}$ the vector of the regression coefficient associated to the covariate vector $\boldsymbol{Z_{ij}}$ for the jth individual in the ith group.

Otherwise, in case of a shared log-normal frailty model, we have for the jth subject in the ith group:

$$\lambda_{ij}(t|\eta_i) = \lambda_0(t) \exp(\eta_i + \boldsymbol{\beta}' \boldsymbol{Z_{ij}})$$

$$\eta_i \sim N(0, \sigma^2)$$

From now on, you can also consider time-varying effects covariates in your model, see `timedep` function for more details.

Joint Frailty model

Fit a joint either with gamma or log-normal frailty model for recurrent and terminal events using a penalized likelihood estimation on the hazard function or a parametric estimation. Right-censored data and strata (up to 6 levels) for the recurrent event part are allowed. Left-truncated data is not possible. Joint frailty models allow studying, jointly, survival processes of recurrent and terminal events, by considering the terminal event as an informative censoring.

There is two kinds of joint frailty models that can be fitted with `frailtyPenal` :

- The first one (Rondeau et al. 2007) includes a common frailty term to the individuals (ω_i) for the two rates which will take into account the heterogeneity in the data, associated with unobserved covariates. The frailty term acts differently for the two rates (ω_i for the recurrent rate and ω_i^α for the death rate). The covariates could be different for the recurrent rate and death rate.

For the jth recurrence ($j = 1, ..., n_i$) and the ith subject ($i = 1, ..., G$), the joint gamma frailty model for recurrent event hazard function $r_{ij}(.)$ and death rate $\lambda_i(.)$ is :

$$\begin{cases} r_{ij}(t|\omega_i) = \omega_i r_0(t) \exp(\boldsymbol{\beta'_1 Z_i(t)}) & \text{(Recurrent)} \\ \lambda_i(t|\omega_i) = \omega_i^{\alpha} \lambda_0(t) \exp(\boldsymbol{\beta'_2 Z_i(t)}) & \text{(Death)} \end{cases}$$

where $r_0(t)$ (resp. $\lambda_0(t)$) is the recurrent (resp. terminal) event baseline hazard function, $\boldsymbol{\beta_1}$ (resp. $\boldsymbol{\beta_2}$) the regression coefficient vector, $\boldsymbol{Z_i(t)}$ the covariate vector. The random effects of frailties $\omega_i \sim \boldsymbol{\Gamma}(\frac{1}{\theta}, \frac{1}{\theta})$ and are iid.

The joint log-normal frailty model will be :

$$\begin{cases} r_{ij}(t|\eta_i) = r_0(t) \exp(\eta_i + \boldsymbol{\beta'_1 Z_i(t)}) & \text{(Recurrent)} \\ \lambda_i(t|\eta_i) = \lambda_0(t) \exp(\alpha\eta_i + \boldsymbol{\beta'_2 Z_i(t)}) & \text{(Death)} \end{cases}$$

where

$$\eta_i \sim N(0, \sigma^2)$$

- The second one (Rondeau et al. 2011) is quite similar but the frailty term is common to the individuals from a same group. This model is useful for the joint modelling two clustered survival outcomes. This joint models have been developed for clustered semi-competing events. The follow-up of each of the two competing outcomes stops when the event occurs. In this case, j is for the subject and i for the cluster.

$$\begin{cases} r_{ij}(t|u_i) = u_i r_0(t) \exp(\boldsymbol{\beta'_1 Z_{ij}(t)}) & \text{(Time to event)} \\ \lambda_{ij}(t|u_i) = u_i^{\alpha} \lambda_0(t) \exp(\boldsymbol{\beta'_2 Z_{ij}(t)}) & \text{(Death)} \end{cases}$$

It should be noted that in these models it is not recommended to include α parameter as there is not enough information to estimate it and thus there might be convergence problems.

In case of a log-normal distribution of the frailties, we will have :

$$\begin{cases} r_{ij}(t|v_i) = r_0(t) \exp(v_i + \boldsymbol{\beta'_1 Z_{ij}(t)}) & \text{(Time to event)} \\ \lambda_{ij}(t|v_i) = \lambda_0(t) \exp(\alpha v_i + \boldsymbol{\beta'_2 Z_{ij}(t)}) & \text{(Death)} \end{cases}$$

where

$$v_i \sim N(0, \sigma^2)$$

This joint frailty model can also be applied to clustered recurrent events and a terminal event (example on "readmission" data below).

From now on, you can also consider time-varying effects covariates in your model, see `timedep` function for more details.

There is a possibility to use a weighted penalized maximum likelihood approach for nested case-control design, in which risk set sampling is performed based on a single outcome (Jazic et al., *Submitted*).

General Joint Frailty model Fit a general joint frailty model for recurrent and terminal events considering two independent frailty terms. The frailty term u_i represents the unobserved association between recurrences and death. The frailty term v_i is specific to the recurrent event rate. Thus, the general joint frailty model is:

$$\begin{cases} r_{ij}(t|u_i, v_i) = u_i v_i r_0(t) \exp(\boldsymbol{\beta_1' Z_{ij}(t)}) = u_i v_i r_{ij}(t) & \text{(Recurrent)} \\ \lambda_i(t|u_i) = u_i \lambda_0(t) \exp(\boldsymbol{\beta_1' Z_i(t)}) = u_i \lambda_i(t) & \text{(Death)} \end{cases}$$

where the *iid* random effects $\boldsymbol{u_i} \sim \Gamma(\frac{1}{\theta}, \frac{1}{\theta})$ and the *iid* random effects $\boldsymbol{v_i} \sim \Gamma(\frac{1}{\eta}, \frac{1}{\eta})$ are independent from each other. The joint model is fitted using a penalized likelihood estimation on the hazard. Right-censored data and time-varying covariates $\boldsymbol{Z_i}(t)$ are allowed.

Nested Frailty model

Data should be ordered according to cluster and subcluster

Fit a nested frailty model using a Penalized Likelihood on the hazard function or using a parametric estimation. Nested frailty models allow survival studies for hierarchically clustered data by including two iid gamma random effects. Left-truncated and right-censored data are allowed. Stratification analysis is allowed (maximum of strata = 2).

The hazard function conditional on the two frailties v_i and w_{ij} for the kth individual of the jth subgroup of the ith group is :

$$\begin{cases} \lambda_{ijk}(t|v_i, w_{ij}) = v_i w_{ij} \lambda_0(t) exp(\boldsymbol{\beta' X_{ijk}}) \\ v_i \sim \Gamma\left(\frac{1}{\alpha}, \frac{1}{\alpha}\right) \ i.i.d. \ \ \boldsymbol{E}(v_i) = 1 \ \ \boldsymbol{Var}(v_i) = \alpha \\ w_{ij} \sim \Gamma\left(\frac{1}{\eta}, \frac{1}{\eta}\right) \ i.i.d. \ \ \boldsymbol{E}(w_{ij}) = 1 \ \ \boldsymbol{Var}(w_{ij}) = \eta \end{cases}$$

where $\lambda_0(t)$ is the baseline hazard function, X_{ijk} denotes the covariate vector and β the corresponding vector of regression parameters.

Joint Nested Frailty Model

Fit a joint model for recurrent and terminal events using a penalized likelihood on the hazard functions or a parametric estimation. Right-censored data are allowed but left-truncated data and stratified analysis are not allowed.

Joint nested frailty models allow studying, jointly, survival processes of recurrent and terminal events for hierarchically clustered data, by considering the terminal event as an informative censoring and by including two iid gamma random effects.

The joint nested frailty model includes two shared frailty terms, one for the subgroup (u_{fi}) and one for the group (w_f) into the hazard functions. This random effects account the heterogeneity in the data, associated with unobserved covariates. The frailty terms act differently for the two rates (u_{fi}, w_f^ξ for the recurrent rate and u_{fi}^α, w_i for the terminal event rate). The covariates could be different for the recurrent rate and death rate.

For the jth recurrence (j = 1, ..., n_i) of the ith individual (i = 1, ..., m_f) of the fth group (f = 1, ..., n), the joint nested gamma frailty model for recurrent event hazard function $r_{fij}(.)$ and for terminal event hazard function λ_{fi} is :

$$\begin{cases} r_{fij}(t|\omega_f, u_{fi}, \boldsymbol{X_{fij}}) = r_0(t) u_{fi} \omega_f^\xi \exp(\boldsymbol{\beta' X_{fij}}) & \text{(Recurrent)} \\ \lambda_{fi}(t|\omega_f, u_{fi}, \boldsymbol{X_{fij}}) = \lambda_0(t) u_{fi}^\alpha \omega_f \exp(\boldsymbol{\gamma' X_{fi}}) & \text{(Death)} \end{cases}$$

where $r_0(t)$(resp. $\lambda_0(t)$) is the recurrent (resp. terminal) event baseline hazard function, β (resp. γ) the regression coefficient vector, $\boldsymbol{X_{fij}}(t)$ the covariates vector. The random effects are

$$\omega_f \sim \Gamma\left(\frac{1}{\eta}, \frac{1}{\eta}\right)$$

and

$$u_{fi} \sim \Gamma\left(\frac{1}{\theta}, \frac{1}{\theta}\right)$$

Usage

```
frailtyPenal(formula, formula.terminalEvent, data, recurrentAG = FALSE,
cross.validation = FALSE, jointGeneral,n.knots, kappa, maxit = 300, hazard =
"Splines", nb.int, RandDist = "Gamma", nb.gh, nb.gl, betaknots = 1, betaorder = 3,
initialize = TRUE, init.B, init.Theta, init.Alpha, Alpha, init.Ksi, Ksi,
init.Eta, LIMparam = 1e-3, LIMlogl = 1e-3, LIMderiv = 1e-3, print.times =
TRUE)
```

Arguments

formula   a formula object, with the response on the left of a $\sim$ operator, and the terms on the right. The response must be a survival object as returned by the 'Surv' function like in survival package. In case of interval-censored data, the response must be an object as returned by the 'SurvIC' function from this package. Interactions are possible using * or :.

formula.terminalEvent

       only for joint and joint nested frailty models : a formula object, only requires terms on the right to indicate which variables are modelling the terminal event. Interactions are possible using * or :.

data   a 'data.frame' with the variables used in 'formula'.

recurrentAG   Logical value. Is Andersen-Gill model fitted? If so indicates that recurrent event times with the counting process approach of Andersen and Gill is used. This formulation can be used for dealing with time-dependent covariates. The default is FALSE.

cross.validation

       Logical value. Is cross validation procedure used for estimating smoothing parameter in the penalized likelihood estimation? If so a search of the smoothing parameter using cross validation is done, with kappa as the seed. The cross validation is not implemented for several strata, neither for interval-censored data. The cross validation has been implemented for a Cox proportional hazard model, with no covariates. The default is FALSE.

jointGeneral   Logical value. Does the model include two independent random effects? If so, this will fit a general joint frailty model with an association between the recurrent events and a terminal event (explained by the variance θ) and an association amongst the recurrent events (explained by the variance η).

n.knots   integer giving the number of knots to use. Value required in the penalized likelihood estimation. It corresponds to the (n.knots+2) splines functions for the approximation of the hazard or the survival functions. We estimate I or M-splines of order 4. When the user set a number of knots equals to k (n.knots=k) then the number of interior knots is (k-2) and the number of splines is (k-2)+order. Number of knots must be between 4 and 20. (See Note)

kappa   positive smoothing parameter in the penalized likelihood estimation. In a stratified shared model, this argument must be a vector with kappas for both strata. In a stratified joint model, this argument must be a vector with kappas for both strata for recurrent events plus one kappa for terminal event. The coefficient kappa of the integral of the squared second derivative of hazard function in

the fit (penalized log likelihood). To obtain an initial value for kappa, a solution is to fit the corresponding shared frailty model using cross validation (See cross.validation). We advise the user to identify several possible tuning parameters, note their defaults and look at the sensitivity of the results to varying them. Value required. (See Note).

maxit   maximum number of iterations for the Marquardt algorithm. Default is 300

hazard   Type of hazard functions: "Splines" for semiparametric hazard functions using equidistant intervals or "Splines-per" using percentile with the penalized likelihood estimation, "Piecewise-per" for piecewise constant hazard function using percentile (not available for interval-censored data), "Piecewise-equi" for piecewise constant hazard function using equidistant intervals, "Weibull" for parametric Weibull functions. Default is "Splines". In case of jointGeneral = TRUE or if a joint nested frailty model is fitted, only hazard = "Splines" can be chosen.

nb.int   Number of time intervals (between 1 and 20) for the parametric hazard functions ("Piecewise-per", "Piecewise-equi"). In a joint model, you need to specify a number of time interval for both recurrent hazard function and the death hazard function (vector of length 2).

RandDist   Type of random effect distribution: "Gamma" for a gamma distribution, "LogN" for a log-normal distribution. Default is "Gamma". Not implemented for nested model. If jointGeneral = TRUE or if a joint nested frailty model is fitted, the log-normal distribution cannot be chosen.

nb.gh   Number of nodes for the Gaussian-Hermite quadrature. It can be chosen among 5, 7, 9, 12, 15, 20 and 32. The default is 20 if hazard = "Splines", 32 otherwise.

nb.gl   Number of nodes for the Gaussian-Laguerre quadrature. It can be chosen between 20 and 32. The default is 20 if hazard = "Splines", 32 otherwise.

betaknots   Number of inner knots used for the estimation of B-splines. Default is 1. See 'timedep' function for more details. Not implemented for nested and joint nested frailty models.

betaorder   Order of the B-splines. Default is cubic B-splines (order = 3). See 'timedep' function for more details. Not implemented for nested and joint nested frailty models.

initialize   Logical value, only for joint nested frailty models. Option TRUE indicates fitting an appropriate standard joint frailty model (without group effect, only the subgroup effect) to provide initial values for the joint nested model. Default is TRUE.

init.B   A vector of initial values for regression coefficients. This vector should be of the same size as the whole vector of covariates with the first elements for the covariates related to the recurrent events and then to the terminal event (interactions in the end of each component). Default is 0.1 for each (for Cox and shared model) or 0.5 (for joint and joint nested frailty models).

init.Theta   Initial value for variance of the frailties.

init.Alpha   Only for joint and joint nested frailty models : initial value for parameter alpha.

Alpha   Only for joint and joint nested frailty model : input "None" so as to fit a joint model without the parameter alpha.

init.Ksi	Only for joint nested frailty model : initial value for parameter ξ.
Ksi	Only for joint nested frailty model : input ″None″ indicates a joint nested frailty model without the parameter ξ.
init.Eta	Only for general joint and joint nested frailty models : initial value for the variance η of the frailty v_i (general joint model) and of the frailty ω_i (joint nested frailty model).
LIMparam	Convergence threshold of the Marquardt algorithm for the parameters (see Details), 10^{-3} by default.
LIMlogl	Convergence threshold of the Marquardt algorithm for the log-likelihood (see Details), 10^{-3} by default.
LIMderiv	Convergence threshold of the Marquardt algorithm for the gradient (see Details), 10^{-3} by default.
print.times	a logical parameter to print iteration process. Default is TRUE.

Details

Typical usages are for a Cox model

```
frailtyPenal(Surv(time,event)~var1+var2, data, \dots)
```

for a shared model

```
frailtyPenal(Surv(time,event)~cluster(group)+var1+var2, data,
\dots)
```

for a joint model

```
frailtyPenal(Surv(time,event)~cluster(group)+var1+var2+
var3+terminal(death), formula.terminalEvent=~ var1+var4, data, \dots)
```

for a joint model for clustered data

```
frailtyPenal(Surv(time,event)~cluster(group)+num.id(group2)+
var1+var2+var3+terminal(death), formula.terminalEvent=~var1+var4, data,
\dots)
```

for a joint model for data from nested case-control studies

```
frailtyPenal(Surv(time,event)~cluster(group)+num.id(group2)+
var1+var2+var3+terminal(death)+wts(wts.ncc),
formula.terminalEvent=~var1+var4, data, \dots)
```

for a nested model

```
frailtyPenal(Surv(time,event)~cluster(group)+subcluster(sbgroup)+
var1+var2, data, \dots)
```

for a joint nested frailty model

```
frailtyPenal(Surv(time,event)~cluster(group)+subcluster(sbgroup)+
var1+var2++terminal(death), formula.terminalEvent=~var1+var4, data, \dots)
```

The estimated parameter are obtained using the robust Marquardt algorithm (Marquardt, 1963) which is a combination between a Newton-Raphson algorithm and a steepest descent algorithm. The iterations are stopped when the difference between two consecutive log-likelihoods was small $(< 10^{-3})$, the estimated coefficients were stable (consecutive values $(< 10^{-3})$, and the gradient small enough $(< 10^{-3})$. When frailty parameter is small, numerical problems may arise. To solve this problem, an alternative formula of the penalized log-likelihood is used (see Rondeau, 2003 for further details). Cubic M-splines of order 4 are used for the hazard function, and I-splines (integrated M-splines) are used for the cumulative hazard function.

The inverse of the Hessian matrix is the variance estimator and to deal with the positivity constraint of the variance component and the spline coefficients, a squared transformation is used and the standard errors are computed by the Δ-method (Knight & Xekalaki, 2000). The smooth parameter can be chosen by maximizing a likelihood cross validation criterion (Joly and other, 1998). The integrations in the full log likelihood were evaluated using Gaussian quadrature. Laguerre polynomials with 20 points were used to treat the integrations on $[0, \infty[$

INITIAL VALUES

The splines and the regression coefficients are initialized to 0.1. In case of shared model, the program fits, firstly, an adjusted Cox model to give new initial values for the splines and the regression coefficients. The variance of the frailty term θ is initialized to 0.1. Then, a shared frailty model is fitted.

In case of a joint frailty model, the splines and the regression coefficients are initialized to 0.5. The program fits an adjusted Cox model to have new initial values for the regression and the splines coefficients. The variance of the frailty term θ and the coefficient α associated in the death hazard function are initialized to 1. Then, it fits a joint frailty model.

In case of a general joint frailty model we need to initialize the `jointGeneral` logical value to TRUE.

In case of a nested model, the program fits an adjusted Cox model to provide new initial values for the regression and the splines coefficients. The variances of the frailties are initialized to 0.1. Then, a shared frailty model with covariates with only subgroup frailty is fitted to give a new initial value for the variance of the subgroup frailty term. Then, a shared frailty model with covariates and only group frailty terms is fitted to give a new initial value for the variance of the group frailties. In a last step, a nested frailty model is fitted.

In case of a joint nested model, the splines and the regression coefficients are initialized to 0.5 and the variances of the frailty terms η and ξ are initialized to 1. If the option `'initialize'` is TRUE, the program fits a joint frailty model to provide initial values for the splines, covariates coefficients, variance θ of the frailty terms and α. The variances of the second frailty term (η) and the second coefficient ξ are initialized to 1. Then, a joint nested frailty model is fitted.

NCC DESIGN

It is possible to fit a joint frailty model for data from nested case-control studies using the approach of weighted penalized maximum likelihood. For this model, only splines can be used for baseline hazards and no time-varying effects of covariates can be included. To accommodate the nested case-control design, the formula for the recurrent events should simply include the special term wts(wts.ncc), where wts.ncc refers to a column of prespecified weights in the data set for every observation. For details, see Jazic et al., *Submitted* (available on request from the package authors).

Value

The following components are included in a 'frailtyPenal' object for each model.

b	sequence of the corresponding estimation of the coefficients for the hazard functions (parametric or semiparametric), the random effects variances and the regression coefficients.
call	The code used for the model.
formula	the formula part of the code used for the model.
coef	the regression coefficients.
cross.Val	Logical value. Is cross validation procedure used for estimating the smoothing parameters in the penalized likelihood estimation?
DoF	Degrees of freedom associated with the "kappa".
groups	the maximum number of groups used in the fit.
kappa	A vector with the smoothing parameters in the penalized likelihood estimation corresponding to each baseline function as components.
loglikPenal	the complete marginal penalized log-likelihood in the semiparametric case.
loglik	the marginal log-likelihood in the parametric case.
n	the number of observations used in the fit.
n.events	the number of events observed in the fit.
n.iter	number of iterations needed to converge.
n.knots	number of knots for estimating the baseline functions in the penalized likelihood estimation.
n.strat	number of stratum.
varH	the variance matrix of all parameters before positivity constraint transformation. Then, the delta method is needed to obtain the estimated variance parameters. That is why some variances don't match with the printed values at the end of the model.
varHIH	the robust estimation of the variance matrix of all parameters.
x	matrix of times where both survival and hazard function are estimated. By default seq(0,max(time),length=99), where time is the vector of survival times.
lam	array (dim=3) of hazard estimates and confidence bands.
surv	array (dim=3) of baseline survival estimates and confidence bands.
median	The value of the median survival and its confidence bands. If there are two stratas or more, the first value corresponds to the value for the first strata, etc.
nbintervR	Number of intervals (between 1 and 20) for the parametric hazard functions ("Piecewise-per", "Piecewise-equi").
npar	number of parameters.
nvar	number of explanatory variables.
LCV	the approximated likelihood cross-validation criterion in the semiparametric case (with H minus the converged Hessian matrix, and l(.) the full log-likelihood).

$$LCV = \frac{1}{n}(trace(H_{pl}^{-1}H) - l(.))$$

AIC   the Akaike information Criterion for the parametric case.

$$AIC = \frac{1}{n}(np - l(.))$$

n.knots.temp	initial value for the number of knots.
shape.weib	shape parameter for the Weibull hazard function.
scale.weib	scale parameter for the Weibull hazard function.
martingale.res	martingale residuals for each cluster.
martingaleCox	martingale residuals for observation in the Cox model.
Frailty	Logical value. Was model with frailties fitted ?
frailty.pred	empirical Bayes prediction of the frailty term (ie, using conditional posterior distributions).
frailty.var	variance of the empirical Bayes prediction of the frailty term (only for gamma frailty models).
frailty.sd	standard error of the frailty empirical Bayes prediction (only for gamma frailty models).
global_chisq	a vector with the values of each multivariate Wald test.
dof_chisq	a vector with the degree of freedom for each multivariate Wald test.
global_chisq.test	
	a binary variable equals to 0 when no multivariate Wald is given, 1 otherwise.
p.global_chisq	a vector with the p_values for each global multivariate Wald test.
names.factor	Names of the "as.factor" variables.
Xlevels	vector of the values that factor might have taken.
contrasts	type of contrast for factor variable.
beta_p.value	p-values of the Wald test for the estimated regression coefficients.

The following components are specific to **shared** models.

equidistant	Indicator for the intervals used the estimation of baseline hazard functions (for splines or pieceiwse-constaant functions) : 1 for equidistant intervals ; 0 for intervals using percentile (note: equidistant = 2 in case of parametric estimation using Weibull distribution).
intcens	Logical value. Indicator if a joint frailty model with interval-censored data was fitted)
theta	variance of the gamma frailty parameter ($\boldsymbol{Var}(\omega_i)$)
sigma2	variance of the log-normal frailty parameter ($\boldsymbol{Var}(\eta_i)$)
linear.pred	linear predictor: uses simply "Beta'X" in the cox proportional hazard model or "Beta'X + log w_i" in the shared gamma frailty models, otherwise uses "Beta'X + w_i" for log-normal frailty distribution.
BetaTpsMat	matrix of time varying-effects and confidence bands (the first column used for abscissa of times)
theta_p.value	p-value of the Wald test for the estimated variance of the gamma frailty.

sigma2_p.value p-value of the Wald test for the estimated variance of the log-normal frailty.

The following components are specific to **joint** models.

intcens	Logical value. Indicator if a joint frailty model with interval-censored data was fitted)
theta	variance of the gamma frailty parameter $(\boldsymbol{Var}(\omega_i))$ or $(\boldsymbol{Var}(u_i))$
sigma2	variance of the log-normal frailty parameter $(\boldsymbol{Var}(\eta_i))$ or $(\boldsymbol{Var}(v_i))$
eta	variance of the second gamma frailty parameter in general joint frailty models $(\boldsymbol{Var}(v_i))$
indic_alpha	indicator if a joint frailty model with α parameter was fitted
alpha	the coefficient α associated with the frailty parameter in the terminal hazard function.
nbintervR	Number of intervals (between 1 and 20) for the recurrent parametric hazard functions ("Piecewise-per", "Piecewise-equi").
nbintervDC	Number of intervals (between 1 and 20) for the death parametric hazard functions ("Piecewise-per", "Piecewise-equi").
nvar	A vector with the number of covariates of each type of hazard function as components.
nvarRec	number of recurrent explanatory variables.
nvarEnd	number of death explanatory variables.
noVar1	indicator of recurrent explanatory variables.
noVar2	indicator of death explanatory variables.
xR	matrix of times where both survival and hazard function are estimated for the recurrent event. By default seq(0,max(time),length=99), where time is the vector of survival times.
xD	matrix of times for the terminal event.
lamR	array (dim=3) of hazard estimates and confidence bands for recurrent event.
lamD	the same value as lamR for the terminal event.
survR	array (dim=3) of baseline survival estimates and confidence bands for recurrent event.
survD	the same value as survR for the terminal event.
martingale.res	martingale residuals for each cluster (recurrent).
martingaledeath.res	
	martingale residuals for each cluster (death).
linear.pred	linear predictor: uses "Beta'X + log w_i" in the gamma frailty model, otherwise uses "Beta'X + eta_i" for log-normal frailty distribution
lineardeath.pred	
	linear predictor for the terminal part : "Beta'X + alpha.log w_i" for gamma, "Beta'X + alpha.eta_i" for log-normal frailty distribution
Xlevels	vector of the values that factor might have taken for the recurrent part.
contrasts	type of contrast for factor variable for the recurrent part.

Xlevels2	vector of the values that factor might have taken for the death part.
contrasts2	type of contrast for factor variable for the death part.
BetaTpsMat	matrix of time varying-effects and confidence bands for recurrent event (the first column used for abscissa of times of recurrence)
BetaTpsMatDc	matrix of time varying-effects and confidence bands for terminal event (the first column used for abscissa of times of death)
alpha_p.value	p-value of the Wald test for the estimated α.
ncc	Logical value whether nested case-control design with weights was used for the joint model.

The following components are specific to **nested** models.

alpha	variance of the cluster effect ($\boldsymbol{Var}(v_i)$)
eta	variance of the subcluster effect ($\boldsymbol{Var}(w_{ij})$)
subgroups	the maximum number of subgroups used in the fit.
frailty.pred.group	
	empirical Bayes prediction of the frailty term by group.
frailty.pred.subgroup	
	empirical Bayes prediction of the frailty term by subgroup.
linear.pred	linear predictor: uses "Beta'X + log v_i.w_ij".
subgbyg	subgroup by group.
n.strat	A vector with the number of covariates of each type of hazard function as components.
alpha_p.value	p-value of the Wald test for the estimated variance of the cluster effect.
eta_p.value	p-value of the Wald test for the estimated variance of the subcluster effect.

The following components are specific to **joint nested frailty** models.

theta	variance of the subcluster effect ($\boldsymbol{Var}(u_{fi})$)
eta	variance of the cluster effect ($\boldsymbol{Var}(\omega_f)$)
alpha	the power coefficient α associated with the frailty parameter (u_{fi}) in the terminal event hazard function.
ksi	the power coefficient ξ associated with the frailty parameter (ω_f) in the recurrent event hazard function.
indic_alpha	indicator if a joint frailty model with α parameter was fitted or not.
indic_ksi	indicator if a joint frailty model with ξ parameter was fitted or not.
frailty.fam.pred	
	empirical Bayes prediction of the frailty term by family.
eta_p.value	p-value of the Wald test for the estimated variance of the cluster effect.
alpha_p.value	p-value of the Wald test for the estimated power coefficient α.
ksi_p.value	p-value of the Wald test for the estimated power coefficient ξ.

Note

From a prediction aim, we recommend you to input a data sorted by the group variable with numerical numbers from 1 to n (number of groups). In case of a nested model, we recommend you to input a data sorted by the group variable then sorted by the subgroup variable both with numerical numbers from 1 to n (number of groups) and from 1 to m (number or subgroups). "kappa" and "n.knots" are the arguments that the user have to change if the fitted model does not converge. "n.knots" takes integer values between 4 and 20. But with n.knots=20, the model would take a long time to converge. So, usually, begin first with n.knots=7, and increase it step by step until it converges. "kappa" only takes positive values. So, choose a value for kappa (for instance 10000), and if it does not converge, multiply or divide this value by 10 or 5 until it converges.

gastadj   *Advanced Gastric Cancer dataset*

Description

This meta-analysis was carried out by the GASTRIC (Global Advanced/Adjuvant Stomach Tumor Research international Collaboration) group, using individual data on patients with curatively resected gastric cancer. Data from all published randomized trials, with a patient recruitment end date before 2004, and comparing adjuvant chemotherapy with surgery alone for resectable gastric cancers, were searched electronically. The candidate surrogate endpoint **S** was Desease-free survival time, defined as the time (in days) to relapse, second cancer or dead from any cause. The true endpoint **T** was the overall survival time, defined as the time (in days) from randomization to death of any cause or to the last follow-up.

Usage

```
data(gastadj)
```

Format

This data frame contains the following columns:

trialID The trial in which the patient was treated

patientID The identification number of a patient

trt The treatment indicator, coded as 0 = Control and 1 = Experimental

timeS The candidate surrogate (progression-free survival in days)

statusS Censoring indicator for for Progression-free survival (0 = alive and progression-free, 1 = with progression or dead)

timeT The true endpoint (overall survival time in days)

statusT Censoring indicator for survival time (0 = alive, 1 = dead)

GenfrailtyPenal   *Fit a Shared or a Joint Frailty Generalized Survival Model*

Description

Shared Frailty model

Fit a shared gamma or log-normal frailty model using a semiparametric Penalized Likelihood estimation or parametric estimation on the hazard function. Left-truncated, right-censored data, interval-censored data and strata (up to 6 levels) are allowed. It allows to obtain a non-parametric

smooth hazard of survival function. This approach is different from the partial penalized likelihood approach of Therneau et al.

The hazard function, conditional on the frailty term ω_i, of a shared gamma frailty model for the jth subject in the ith group:

$$\lambda_{ij}(t|\omega_i) = \lambda_0(t)\omega_i \exp(\boldsymbol{\beta}' \boldsymbol{Z_{ij}})$$

$$\omega_i \sim \Gamma\left(\frac{1}{\theta}, \frac{1}{\theta}\right) \quad \boldsymbol{E}(\omega_i) = 1 \quad \boldsymbol{Var}(\omega_i) = \theta$$

where $\lambda_0(t)$ is the baseline hazard function, $\boldsymbol{\beta}$ the vector of the regression coefficient associated to the covariate vector $\boldsymbol{Z_{ij}}$ for the jth individual in the ith group.

Otherwise, in case of a shared log-normal frailty model, we have for the jth subject in the ith group:

$$\lambda_{ij}(t|\eta_i) = \lambda_0(t)\exp(\eta_i + \boldsymbol{\beta}' \boldsymbol{Z_{ij}})$$

$$\eta_i \sim N(0, \sigma^2)$$

From now on, you can also consider time-varying effects covariates in your model, see `timedep` function for more details.

Joint Frailty model

Fit a joint either with gamma or log-normal frailty model for recurrent and terminal events using a penalized likelihood estimation on the hazard function or a parametric estimation. Right-censored data and strata (up to 6 levels) for the recurrent event part are allowed. Left-truncated data is not possible. Joint frailty models allow studying, jointly, survival processes of recurrent and terminal events, by considering the terminal event as an informative censoring.

There is two kinds of joint frailty models that can be fitted with `GenfrailtyPenal` :

- The first one (Rondeau et al. 2007) includes a common frailty term to the individuals (ω_i) for the two rates which will take into account the heterogeneity in the data, associated with unobserved covariates. The frailty term acts differently for the two rates (ω_i for the recurrent rate and ω_i^α for the death rate). The covariates could be different for the recurrent rate and death rate.

For the jth recurrence ($j = 1, ..., n_i$) and the ith subject ($i = 1, ..., G$), the joint gamma frailty model for recurrent event hazard function $r_{ij}(.)$ and death rate $\lambda_i(.)$ is :

$$\begin{cases} r_{ij}(t|\omega_i) = \omega_i r_0(t)\exp(\boldsymbol{\beta_1}' \boldsymbol{Z_i(t)}) & \text{(Recurrent)} \\ \lambda_i(t|\omega_i) = \omega_i^\alpha \lambda_0(t)\exp(\boldsymbol{\beta_2}' \boldsymbol{Z_i(t)}) & \text{(Death)} \end{cases}$$

where $r_0(t)$ (resp. $\lambda_0(t)$) is the recurrent (resp. terminal) event baseline hazard function, $\boldsymbol{\beta_1}$ (resp. $\boldsymbol{\beta_2}$) the regression coefficient vector, $\boldsymbol{Z_i(t)}$ the covariate vector. The random effects of frailties $\omega_i \sim \boldsymbol{\Gamma}(\frac{1}{\theta}, \frac{1}{\theta})$ and are iid.

The joint log-normal frailty model will be :

$$\begin{cases} r_{ij}(t|\eta_i) = r_0(t)\exp(\eta_i + \boldsymbol{\beta_1}' \boldsymbol{Z_i(t)}) & \text{(Recurrent)} \\ \lambda_i(t|\eta_i) = \lambda_0(t)\exp(\alpha\eta_i + \boldsymbol{\beta_2}' \boldsymbol{Z_i(t)}) & \text{(Death)} \end{cases}$$

where

$$\eta_i \sim N(0, \sigma^2)$$

- The second one (Rondeau et al. 2011) is quite similar but the frailty term is common to the individuals from a same group. This model is useful for the joint modelling two clustered survival outcomes. This joint models have been developed for clustered semi-competing events. The follow-up of each of the two competing outcomes stops when the event occurs. In this case, j is for the subject and i for the cluster.

$$\begin{cases} r_{ij}(t|u_i) = u_i r_0(t) \exp(\boldsymbol{\beta_1'} \boldsymbol{Z_{ij}(t)}) & \text{(Time to event)} \\ \lambda_{ij}(t|u_i) = u_i^{\alpha} \lambda_0(t) \exp(\boldsymbol{\beta_2'} \boldsymbol{Z_{ij}(t)}) & \text{(Death)} \end{cases}$$

It should be noted that in these models it is not recommended to include α parameter as there is not enough information to estimate it and thus there might be convergence problems.

In case of a log-normal distribution of the frailties, we will have :

$$\begin{cases} r_{ij}(t|v_i) = r_0(t) \exp(v_i + \boldsymbol{\beta_1'} \boldsymbol{Z_{ij}(t)}) & \text{(Time to event)} \\ \lambda_{ij}(t|v_i) = \lambda_0(t) \exp(\alpha v_i + \boldsymbol{\beta_2'} \boldsymbol{Z_{ij}(t)}) & \text{(Death)} \end{cases}$$

where

$$v_i \sim N(0, \sigma^2)$$

This joint frailty model can also be applied to clustered recurrent events and a terminal event (example on "readmission" data below).

From now on, you can also consider time-varying effects covariates in your model, see `timedep` function for more details.

There is a possibility to use a weighted penalized maximum likelihood approach for nested case-control design, in which risk set sampling is performed based on a single outcome (Jazic et al., *Submitted*).

General Joint Frailty model Fit a general joint frailty model for recurrent and terminal events considering two independent frailty terms. The frailty term u_i represents the unobserved association between recurrences and death. The frailty term v_i is specific to the recurrent event rate. Thus, the general joint frailty model is:

$$\begin{cases} r_{ij}(t|u_i, v_i) = u_i v_i r_0(t) \exp(\boldsymbol{\beta_1'} \boldsymbol{Z_{ij}(t)}) = u_i v_i r_{ij}(t) & \text{(Recurrent)} \\ \lambda_i(t|u_i) = u_i \lambda_0(t) \exp(\boldsymbol{\beta_1'} \boldsymbol{Z_i(t)}) = u_i \lambda_i(t) & \text{(Death)} \end{cases}$$

where the *iid* random effects $\boldsymbol{u_i} \sim \Gamma(\frac{1}{\theta}, \frac{1}{\theta})$ and the *iid* random effects $\boldsymbol{v_i} \sim \Gamma(\frac{1}{\eta}, \frac{1}{\eta})$ are independent from each other. The joint model is fitted using a penalized likelihood estimation on the hazard. Right-censored data and time-varying covariates $\boldsymbol{Z_i}(t)$ are allowed.

Nested Frailty model

Data should be ordered according to cluster and subcluster

Fit a nested frailty model using a Penalized Likelihood on the hazard function or using a parametric estimation. Nested frailty models allow survival studies for hierarchically clustered data by including two iid gamma random effects. Left-truncated and right-censored data are allowed. Stratification analysis is allowed (maximum of strata = 2).

The hazard function conditional on the two frailties v_i and w_{ij} for the kth individual of the jth subgroup of the ith group is :

$$\begin{cases} \lambda_{ijk}(t|v_i, w_{ij}) = v_i w_{ij} \lambda_0(t) exp(\boldsymbol{\beta}' \boldsymbol{X_{ijk}}) \\ v_i \sim \Gamma\left(\frac{1}{\alpha}, \frac{1}{\alpha}\right) \ i.i.d. \ \ \boldsymbol{E}(v_i) = 1 \ \ \boldsymbol{Var}(v_i) = \alpha \\ w_{ij} \sim \Gamma\left(\frac{1}{\eta}, \frac{1}{\eta}\right) \ i.i.d. \ \ \boldsymbol{E}(w_{ij}) = 1 \ \ \boldsymbol{Var}(w_{ij}) = \eta \end{cases}$$

where $\lambda_0(t)$ is the baseline hazard function, X_{ijk} denotes the covariate vector and β the corresponding vector of regression parameters.

Joint Nested Frailty Model

Fit a joint model for recurrent and terminal events using a penalized likelihood on the hazard functions or a parametric estimation. Right-censored data are allowed but left-truncated data and stratified analysis are not allowed.

Joint nested frailty models allow studying, jointly, survival processes of recurrent and terminal events for hierarchically clustered data, by considering the terminal event as an informative censoring and by including two iid gamma random effects.

The joint nested frailty model includes two shared frailty terms, one for the subgroup (u_{fi}) and one for the group (w_f) into the hazard functions. This random effects account the heterogeneity in the data, associated with unobserved covariates. The frailty terms act differently for the two rates (u_{fi}, w_f^ξ for the recurrent rate and u_{fi}^α, w_i for the terminal event rate). The covariates could be different for the recurrent rate and death rate.

For the jth recurrence (j = 1, ..., n_i) of the ith individual (i = 1, ..., m_f) of the fth group (f = 1, ..., n), the joint nested gamma frailty model for recurrent event hazard function $r_{fij}(.)$ and for terminal event hazard function λ_{fi} is :

$$\begin{cases} r_{fij}(t|\omega_f, u_{fi}, \boldsymbol{X_{fij}}) = r_0(t) u_{fi} \omega_f^\xi \exp(\boldsymbol{\beta}' \boldsymbol{X_{fij}}) & \text{(Recurrent)} \\ \lambda_{fi}(t|\omega_f, u_{fi}, \boldsymbol{X_{fij}}) = \lambda_0(t) u_{fi}^\alpha \omega_f \exp(\boldsymbol{\gamma}' \boldsymbol{X_{fi}}) & \text{(Death)} \end{cases}$$

where $r_0(t)$(resp. $\lambda_0(t)$) is the recurrent (resp. terminal) event baseline hazard function, β (resp. γ) the regression coefficient vector, $\boldsymbol{X_{fij}}(t)$ the covariates vector. The random effects are

$$\omega_f \sim \Gamma\left(\frac{1}{\eta}, \frac{1}{\eta}\right)$$

and

$$u_{fi} \sim \Gamma\left(\frac{1}{\theta}, \frac{1}{\theta}\right)$$

Usage

```
GenfrailtyPenal(formula, formula.terminalEvent, data, recurrentAG = FALSE,
family, hazard = "Splines", n.knots, kappa, betaknots = 1, betaorder = 3,
RandDist = "Gamma", init.B, init.Theta, init.Alpha, Alpha, maxit = 300,
nb.gh, nb.gl, LIMparam = 1e-3, LIMlogl = 1e-3, LIMderiv = 1e-3, print.times = TRUE,
cross.validation, jointGeneral, nb.int, initialize, init.Ksi, Ksi, init.Eta)
```

Arguments

formula	A formula object, with the response on the left of a $\sim$ operator, and the terms on the right. The response must be a survival object as returned by the 'Surv' function like in survival package. Interactions are possible using ' * ' or ' : '.
formula.terminalEvent	
	Only for joint frailty models: a formula object, only requires terms on the right to indicate which variables are used for the terminal event. Interactions are possible using ' * ' or ' : '.
data	A 'data.frame' with the variables used in 'formula'.
recurrentAG	Logical value. Is Andersen-Gill model fitted? If so indicates that recurrent event times with the counting process approach of Andersen and Gill is used. This formulation can be used for dealing with time-dependent covariates. The default is FALSE.
family	Type of Generalized Survival Model to fit. "PH" for a proportional hazards model, "AH" for an additive hazards model, "PO" for a proportional odds model and "probit" for a probit model. A vector of length 2 is expected for joint models (e.g., family=c("PH","PH")).
hazard	Type of hazard functions: "Splines" for semi-parametric hazard functions using equidistant intervals, or "parametric" for parametric distribution functions. In case of family="PH" or family="AH", the "parametric" option corresponds to a Weibull distribution. In case of family="PO" and family="probit", the "parametric" option corresponds to a log-logistic and a log-normal distribution, respectively. So far, the "Splines" option is only available for PH and AH submodels. Default is "Splines".
n.knots	Integer giving the number of knots to use. Value required in the penalized likelihood estimation. It corresponds to the n.knots+2 splines functions for the approximation of the hazard or the survival functions. We estimate I- or M-splines of order 4. When the user set a number of knots equals to k (i.e. n.knots=k), then the number of interior knots is k-2 and the number of splines is (k-2)+order. Number of knots must be between 4 and 20. (See Note)
kappa	Positive smoothing parameter in the penalized likelihood estimation. The coefficient kappa tunes the intensity of the penalization (the integral of the squared second derivative of hazard function). In a stratified shared model, this argument must be a vector with kappas for both strata. In a stratified joint model, this argument must be a vector with kappas for both strata for recurrent events plus one kappa for terminal event. We advise the user to identify several possible tuning parameters, note their defaults and look at the sensitivity of the results to varying them. Value required. (See Note).
betaknots	Number of inner knots used for the B-splines time-varying coefficient estimation. Default is 1. See 'timedep' function for more details.
betaorder	Order of the B-splines used for the time-varying coefficient estimation. Default is cubic B-splines (order=3). See 'timedep' function for more details. Not implemented for Proportional Odds and Probit submodels.
RandDist	Type of random effect distribution: "Gamma" for a gamma distribution, and "LogN" for a log-normal distribution (not implemented yet). Default is "Gamma".

init.B	A vector of initial values for regression coefficients. This vector should be of the same size as the whole vector of covariates with the first elements for the covariates related to the recurrent events and then to the terminal event (interactions in the end of each component). Default is 0.1 for each (for Generalized Survival and Shared Frailty Models) or 0.5 (for Generalized Joint Frailty Models).
init.Theta	Initial value for frailty variance.
init.Alpha	Only for Generalized Joint Frailty Models: initial value for parameter alpha.
Alpha	Only for Generalized Joint Frailty Models: input "None" so as to fit a joint model without the parameter alpha.
maxit	Maximum number of iterations for the Marquardt algorithm. Default is 300
nb.gh	Number of nodes for the Gaussian-Hermite quadrature. It can be chosen among 5, 7, 9, 12, 15, 20 and 32. The default is 20 if `hazard="Splines"`, 32 otherwise.
nb.gl	Number of nodes for the Gaussian-Laguerre quadrature. It can be chosen between 20 and 32. The default is 20 if `hazard="Splines"`, 32 otherwise.
LIMparam	Convergence threshold of the Marquardt algorithm for the parameters (see Details), 10^{-3} by default.
LIMlogl	Convergence threshold of the Marquardt algorithm for the log-likelihood (see Details), 10^{-3} by default.
LIMderiv	Convergence threshold of the Marquardt algorithm for the gradient (see Details), 10^{-3} by default.
print.times	A logical parameter to print iteration process. Default is TRUE.
cross.validation	
	Not implemented yet for the generalized settings.
jointGeneral	Not implemented yet for the generalized settings.
nb.int	Not implemented yet for the generalized settings.
initialize	Not implemented yet for the generalized settings.
init.Ksi	Not implemented yet for the generalized settings.
Ksi	Not implemented yet for the generalized settings.
init.Eta	Not implemented yet for the generalized settings.

Details

TYPICAL USES

For a Generalized Survival Model:

```
GenfrailtyPenal(
formula=Surv(time,event)~var1+var2,
data, family, \dots)
```

For a Shared Frailty Generalized Survival Model:

```
GenfrailtyPenal(
formula=Surv(time,event)~cluster(group)+var1+var2,
data, family, \dots)
```

For a Joint Frailty Generalized Survival Model:

```
GenfrailtyPenal(
formula=Surv(time,event)~cluster(group)+var1+var2+var3+terminal(death),
formula.terminalEvent= ~var1+var4,
data, family, \dots)
```

OPTIMIZATION ALGORITHM

The estimated parameters are obtained using the robust Marquardt algorithm (Marquardt, 1963) which is a combination between a Newton-Raphson algorithm and a steepest descent algorithm. The iterations are stopped when the difference between two consecutive log-likelihoods is small ($< 10^{-3}$), the estimated coefficients are stable (consecutive values $< 10^{-3}$, and the gradient small enough ($< 10^{-3}$). When the frailty variance is small, numerical problems may arise. To solve this problem, an alternative formula of the penalized log-likelihood is used (see Rondeau, 2003 for further details). For Proportional Hazards and Additive Hazards submodels, cubic M-splines of order 4 can be used to estimate the hazard function. In this case, I-splines (integrated M-splines) are used to compute the cumulative hazard function.

The inverse of the Hessian matrix is the variance estimator. To deal with the positivity constraint of the variance component and the spline coefficients, a squared transformation is used and the standard errors are computed by the Δ-method (Knight & Xekalaki, 2000). The integrations in the full log likelihood are evaluated using Gaussian quadrature. Laguerre polynomials with 20 points are used to treat the integrations on $[0, \infty[$.

INITIAL VALUES

In case of a shared frailty model, the splines and the regression coefficients are initialized to 0.1. The program fits, firstly, an adjusted Cox model to give new initial values for the splines and the regression coefficients. The variance of the frailty term θ is initialized to 0.1. Then, a shared frailty model is fitted.

In case of a joint frailty model, the splines and the regression coefficients are initialized to 0.5. The program fits firstly, an adjusted Cox model to have new initial values for the splines and the regression coefficients. The variance of the frailty term θ and the association parameter α are initialized to 1. Then, a joint frailty model is fitted.

Value

The following components are included in a 'frailtyPenal' object for each model.

b	Sequence of the corresponding estimation of the coefficients for the hazard functions (parametric or semiparametric), the random effects variances and the regression coefficients.
call	The code used for the model.
formula	The formula part of the code used for the model.
n	The number of observations used in the fit.
groups	The maximum number of groups used in the fit.
n.events	The number of events observed in the fit.
n.eventsbygrp	A vector of length the number of groups giving the number of observed events in each group.

loglik	The marginal log-likelihood in the parametric case.
loglikPenal	The marginal penalized log-likelihood in the semiparametric case.
coef	The regression coefficients.
varH	The variance matrix of the regression coefficients before positivity constraint transformation. Then, the delta method is needed to obtain the estimated variance parameters. That is why some variances don't match with the printed values at the end of the model.
varHtotal	The variance matrix of all the parameters before positivity constraint transformation. Then, the delta method is needed to obtain the estimated variance parameters. That is why some variances don't match with the printed values at the end of the model.
varHIH	The robust estimation of the variance matrix of the regression coefficients
varHIHtotal	The robust estimation of the variance matrix of all parameters.
x	Matrix of times where the hazard functions are estimated.
xSu	Matrix of times where the survival functions are estimated.
lam	Array (dim=3) of baseline hazard estimates and confidence bands.
surv	Array (dim=3) of baseline survival estimates and confidence bands.
type	Character string specifying the type of censoring, see the Surv function for more details.
n.strat	Number of strata.
n.iter	Number of iterations needed to converge.
median	The value of the median survival and its confidence bands. If there are two strata or more, the first value corresponds to the value for the first strata, etc.
LCV	The approximated likelihood cross-validation criterion in the semiparametric case. With H (resp. H_{pen}) the hessian matrix of log-likelihood (resp. penalized log-likelihood), EDF = H_{pen}^{-1} H the effective degrees of freedom, $L(\xi,\theta)$ the log-likelihood and n the number of observations, $$LCV = 1/nx(trace(EDF) - L(\xi, \theta)).$$
AIC	The Akaike information Criterion for the parametric case. With p the number of parameters, n the number of observations and $L(\xi,\theta)$ the log-likelihood, $$AIC = 1/nx(p - L(\xi, \theta)).$$
npar	Number of parameters.
nvar	Number of explanatory variables.
typeof	Indicator of the type of hazard functions computed : 0 for "Splines", 2 for "parametric".
istop	Convergence indicator: 1 if convergence is reached, 2 if convergence is not reached, 3 if the hessian matrix is not positive definite, 4 if a numerical problem has occurred in the likelihood calculation

shape.param	Shape parameter for the parametric hazard function (a Weibull distribution is used for proportional and additive hazards models, a log-logistic distribution is used for proportional odds models, a log-normal distribution is used for probit models).
scale.param	Scale parameter for the parametric hazard function.
Names.data	Name of the dataset.
Frailty	Logical value. Was model with frailties fitted ?
linear.pred	Linear predictor: $\beta'X$ in the generalized survival models or $\beta'X + \log(u_i)$ in the shared frailty generalized survival models.
BetaTpsMat	Matrix of time varying-effects and confidence bands (the first column used for abscissa of times).
nvartimedep	Number of covariates with time-varying effects.
Names.vardep	Name of the covariates with time-varying effects.
EPS	Convergence criteria concerning the parameters, the likelihood and the gradient.
family	Type of Generalized Survival Model fitted (0 for PH, 1 for PO, 2 for probit, 3 for AH).
global_chisq.test	
	A binary variable equals to 0 when no multivariate Wald is given, 1 otherwise.
beta_p.value	p-values of the Wald test for the estimated regression coefficients.
cross.Val	Logical value. Is cross validation procedure used for estimating the smoothing parameters in the penalized likelihood estimation?
DoF	Degrees of freedom associated with the smoothing parameter kappa.
kappa	A vector with the smoothing parameters in the penalized likelihood estimation corresponding to each baseline function as components.
n.knots	Number of knots for estimating the baseline functions in the penalized likelihood estimation.
n.knots.temp	Initial value for the number of knots.
global_chisq	A vector with the values of each multivariate Wald test.
dof_chisq	A vector with the degree of freedom for each multivariate Wald test.
p.global_chisq	A vector with the p-values for each global multivariate Wald test.
names.factor	Names of the "as.factor" variables.
Xlevels	Vector of the values that factor might have taken.

The following components are specific to **shared** models.

equidistant	Indicator for the intervals used in the spline estimation of baseline hazard functions : 1 for equidistant intervals ; 0 for intervals using percentile (note: equidistant = 2 in case of parametric estimation).
Names.cluster	Cluster names.
theta	Variance of the gamma frailty parameter, i.e. $\mathrm{Var}(u_i)$.
varTheta	Variance of parameter theta.

theta_p.value   p-value of the Wald test for the estimated variance of the gamma frailty.

The following components are specific to **joint** models.

formula	The formula part of the code used for the recurrent events.
formula.terminalEvent	
	The formula part of the code used for the terminal model.
n.deaths	Number of observed deaths.
n.censored	Number of censored individuals.
theta	Variance of the gamma frailty parameter, i.e. $\text{Var}(u_i)$.
indic_alpha	Indicator if a joint frailty model with α parameter was fitted.
alpha	The coefficient α associated with the frailty parameter in the terminal hazard function.
nvar	A vector with the number of covariates of each type of hazard function as components.
nvarnotdep	A vector with the number of constant effect covariates of each type of hazard function as components.
nvarRec	Number of recurrent explanatory variables.
nvarEnd	Number of death explanatory variables.
noVar1	Indicator of recurrent explanatory variables.
noVar2	Indicator of death explanatory variables.
Names.vardep	Name of the covariates with time-varying effects for the recurrent events.
Names.vardepdc	Name of the covariates with time-varying effects for the terminal event.
xR	Matrix of times where both survival and hazard function are estimated for the recurrent event.
xD	Matrix of times for the terminal event.
lamR	Array (dim=3) of hazard estimates and confidence bands for recurrent event.
lamD	The same value as lamR for the terminal event.
survR	Array (dim=3) of baseline survival estimates and confidence bands for recurrent event.
survD	The same value as survR for the terminal event.
nb.gh	Number of nodes for the Gaussian-Hermite quadrature.
nb.gl	Number of nodes for the Gaussian-Laguerre quadrature.
medianR	The value of the median survival for the recurrent events and its confidence bands.
medianD	The value of the median survival for the terminal event and its confidence bands.
names.factor	Names of the "as.factor" variables for the recurrent events.
names.factordc	Names of the "as.factor" variables for the terminal event.
Xlevels	Vector of the values that factor might have taken for the recurrent events.
Xlevels2	Vector of the values that factor might have taken for the terminal event.

`linear.pred`	Linear predictor for the recurrent part: $\beta'X + \log(u_i)$.
`lineardeath.pred`	
	Linear predictor for the terminal part: $\beta'X + \alpha \times \log(u_i)$.
`Xlevels`	Vector of the values that factor might have taken for the recurrent part.
`Xlevels2`	vector of the values that factor might have taken for the death part.
`BetaTpsMat`	Matrix of time varying-effects and confidence bands for recurrent event (the first column used for abscissa of times of recurrence).
`BetaTpsMatDc`	Matrix of time varying-effects and confidence bands for terminal event (the first column used for abscissa of times of death).
`alpha_p.value`	p-value of the Wald test for the estimated α.

Note

In the flexible semiparametric case, smoothing parameters `kappa` and number of knots `n.knots` are the arguments that the user have to change if the fitted model does not converge. `n.knots` takes integer values between 4 and 20. But with `n.knots=20`, the model would take a long time to converge. So, usually, begin first with `n.knots=7`, and increase it step by step until it converges. `kappa` only takes positive values. So, choose a value for kappa (for instance 10000), and if it does not converge, multiply or divide this value by 10 or 5 until it converges.

hazard	*Hazard function.*

Description

Let t be a continuous variable, we determine the value of the hazard function to t after run fit.

Usage

```
hazard(t, ObjFrailty)
```

Arguments

t	time for hazard function.
ObjFrailty	an object from the frailtypack fit.

Value

return the value of hazard function in t.

Examples

```
## Not run:

#-- a fit Shared
data(readmission)
fit.shared <- frailtyPenal(Surv(time,event)~dukes+cluster(id)+
strata(sex),n.knots=10,kappa=c(10000,10000),data=readmission)

#-- calling survival
hazard(20,fit.shared)

## End(Not run)

jointSurrCopSimul   *Generate survival times for two endpoints using the joint frailty-copula model for surrogacy*

Description

Date are generated from the one-step joint frailty-copula model, under the Claton copula function (see `jointSurroCopPenal` for more details)

Usage

```
jointSurrCopSimul(
  n.obs = 600,
  n.trial = 30,
  prop.cens = 0,
  cens.adm = 549,
  alpha = 1.5,
  gamma = 2.5,
  sigma.s = 0.7,
  sigma.t = 0.7,
  cor = 0.9,
  betas = c(-1.25, 0.5),
  betat = c(-1.25, 0.5),
  frailt.base = 1,
  lambda.S = 1.3,
  nu.S = 0.0025,
  lambda.T = 1.1,
  nu.T = 0.0025,
  ver = 2,
  typeOf = 1,
  equi.subj.trial = 1,
  equi.subj.trt = 1,
  prop.subj.trial = NULL,
  prop.subj.trt = NULL,
  full.data = 0,
  random.generator = 1,
  random = 0,
  random.nb.sim = 0,
  seed = 0,
  nb.reject.data = 0,
  thetacopule = 6,
  filter.surr = c(1, 1),
  filter.true = c(1, 1),
  covar.names = "trt",
  pfs = 0
)
```

Arguments

n.obs	Number of considered subjects. The default is 600.
n.trial	Number of considered trials. The default is 30.
prop.cens	A value between 0 and 1, 1-prop.cens is the minimum proportion of people who are randomly censored. Represents the quantile to use for generating the random censorship time. In this case, the censorship time follows a uniform distribution in 1 and (prop.cens)ieme percentile of the generated death times. If this argument is set to 0, the fix censorship is considered. The default is 0.
cens.adm	Censorship time. If argument prop.cens is set to 0, it represents the administrative censorship time, else it represents the fix censoring time. The default is 549, for about 40% of fix censored subjects.
alpha	Fixed value for α. The default is 1.5.
gamma	Fixed value for γ. The default is 2.5.
sigma.s	Fixed value for $\sigma^2_{v_S}$. The default is 0.7.
sigma.t	Fixed value for $\sigma^2_{v_T}$. The default is 0.7.
cor	Desired level of correlation between v_{S_i} and v_{T_i}. $R^2_{trial} = cor^2$. The default is 0.8.
betas	Vector of the fixed effects for β_S . The size must be equal to ver The default is c(-1.25,0.5).
betat	Vector of the fixed effects for β_T . The size must be equal to ver The default is c(-1.25,0.5).
frailt.base	Considered heterogeneity on the baseline risk (1) or not (0). The default is 1.
lambda.S	Desired scale parameter for the Weibull distribution associated with the Surrogate endpoint. The default is 1.8.
nu.S	Desired shape parameter for the Weibull distribution associated with the Surrogate endpoint. The default is 0.0045.
lambda.T	Desired scale parameter for the Weibull distribution associated with the True endpoint. The default is 3.
nu.T	Desired shape parameter for the Weibull distribution associated with the True endpoint. The default is 0.0025.
ver	Number of covariates. The mandatory covariate is the treatment arm. The default is 2.
typeOf	Type of joint model used for data generation: 0 = classical joint model with a shared individual frailty effect (Rondeau, 2007), 1 = joint frailty-copula model with shared frailty effects u_i and two correlated random effects treatment-by-trial interaction (v_{S_i}, v_{T_i}), see [jointSurroCopPenal]().
equi.subj.trial	
	A binary variable that indicates if the same proportion of subjects should be included per trial (1) or not (0). If 0, the proportions of subject per trial are required with parameter prop.subj.trial.
equi.subj.trt	A binary variable that indicates if the same proportion of subjects is randomized per trial (1) or not (0). If 0, the proportions of subject per trial are required with parameter prop.subj.trt.

prop.subj.trial

                The proportions of subjects per trial. Requires if `equi.subj.trial = 0`.

prop.subj.trt   The proportions of randomized subject per trial. Requires if `equi.subj.trt = 0`.

full.data   Specified if you want the function to return the full dataset (1), including the random effects, or the restictive dataset (0) with at least 7 columns as required for the function [jointSurroCopPenal](#).

random.generator

                The random number generator used by the Fortran compiler, 1 for the intrinsec subroutine Random_number and 2 for the subroutine uniran(). The default is 1.

random   A binary that says if we reset the random number generation with a different environment at each call (1) or not (0). If it is set to 1, we use the computer clock as seed. In the last case, it is not possible to reproduce the generated datasets. The default is 0. Required if `random.generator` is set to 1.

random.nb.sim   required if `random.generator` is set to 1, and if `random` is set to 1.

seed   The seed to use for data (or samples) generation. Required if the argument `random.generator` is set to 1. Must be a positive value. If negative, the program do not account for seed. The default is 0.

nb.reject.data Number of generation to reject before the considered dataset. This parameter is required when data generation is for simulation. With a fixed parameter and `random.generator` set to 1, all ganerated data are the same. By varying this parameter, different datasets are obtained during data generations. The default value is 0, in the event of one dataset.

thetacopule   The desired value for the copula parameter. The default is 6.

filter.surr   Vector of size the number of covariates, with the i-th element that indicates if the hazard for surrogate is adjusted on the i-th covariate (code 1) or not (code 0). By default, 2 covariates are considered.

filter.true   Vector defines as `filter.surr`, for the true endpoint. `filter.true` and `filter.surr` should have the same size

covar.names   Vector of the names of covariables. By default it contains "trt" for the tratment arm. Should contains the names of all covarites wished in the generated dataset.

pfs   Is used to specify if the time to progression should be censored by the death time (0) or not (1). The default is 0. In the event with pfs set to 1, death is included in the surrogate endpoint as in the definition of PFS or DFS.

Details

We just considered in this generation, the Gaussian random effects. If the parameter `full.data` is set to 1, this function return a list containning severals parameters, including the generated random effects. The desired individual level correlation (Kendall's τ) depend on the values of the copula parameter θ, given that $\tau = \theta/(\theta + 2)$ under the clayton copula model.

Value

This function returns if the parameter `full.data` is set to 0, a `data.frame` with columns :

patientID	A numeric, that represents the patient's identifier, must be unique;
trialID	A numeric, that represents the trial in which each patient was randomized;
trt	The treatment indicator for each patient, with 1 = treated, 0 = untreated;
timeS	The follow up time associated with the surrogate endpoint;
statusS	The event indicator associated with the surrogate endpoint. Normally 0 = no event, 1 = event;
timeT	The follow up time associated with the true endpoint;
statusT	The event indicator associated with the true endpoint. Normally 0 = no event, 1 = event;

and other covariates named `Var2`, `var3`, `...`, `var[ver-1]` if `ver > 1`. If the argument `full.data` is set to 1, additionnal colums corresponding to random effects u_i , v_{S_i} and v_{T_i} are returned.

jointSurroCopPenal   *Fit the one-step Joint frailty-copula model for evaluating a canditate*
                            surrogate endpoint

Description

Joint Frailty-Copula model for Surrogacy definition

Fit the one-step Joint surrogate model for the evaluation of a canditate surrogate endpoint, with different integration methods on the random effects, using a semiparametric penalized likelihood estimation. This approach extends that of Burzykowski et al. (2001) by including in the bivariate copula model the random effects treatment-by-trial interaction.

Assume S_{ij} and T_{ij} the failure times associated respectively with the surrogate and the true endpoints, for subject j $(j = 1, \ldots, n_i)$ belonging to the trial $i (i = 1, \ldots, G)$.

Let $\mathbf{v}_i = (u_i, v_{Si}, v_{Ti})$ be the vector of trial level random effects; $\mathbf{Z}_{S,ij} = (Z_{Sij1}, \cdots, Z_{Sijp})'$ and $\mathbf{Z}_{T,ij} = (Z_{Tij1}, \cdots, Z_{Tijp})'$ be covariates associated with S_{ij} and T_{ij} The joint frailty-copula model is defined as follows:

$$
\begin{aligned}
\bar{F}(s_{ij}, t_{ij}|\mathbf{Z}_{S,ij}, \mathbf{Z}_{T,ij}, \mathbf{v}_i) &= P(S_{ij} > s_{ij}, T_{ij} > t_{ij}|\mathbf{Z}_{S,ij}, \mathbf{Z}_{T,ij}, \mathbf{v}_i) \\
&= \varphi_\theta[\varphi_\theta^{-1}(\bar{F}(s_{ij}|\mathbf{Z}_{S,ij}, u_i, v_{Si})) + \varphi_\theta^{-1}(\bar{F}(t_{ij}|\mathbf{Z}_{T,ij}, u_i, v_{Ti}))]
\end{aligned}
$$

where,

$\varphi_\theta : [0, \infty) \rightarrow [0, 1]$ the generator of a parametric Archimedean copula family

and the conditional survival functions are given by

$$
\bar{F}_{S,ij}(s_{ij}|\mathbf{Z}_{S,ij}, u_i, v_{Si}) = \exp\left\{ -\int_0^{s_{ij}} \lambda_{0S}(x)\exp\left(u_i + v_{Si}Z_{ij1} + \boldsymbol{\beta}_S\mathbf{Z}_{S,ij}\right)dx\right\}
$$

$$
\bar{F}_{T,ij}(t_{ij}|\mathbf{Z}_{T,ij}, u_i, v_{Ti}) = \exp\left\{ -\int_0^{t_{ij}} \lambda_{0T}(x)\exp\left(\alpha u_i + v_{Ti}Z_{ij1} + \boldsymbol{\beta}_T\mathbf{Z}_{T,ij}\right)dx\right\}
$$

in which

$$
u_i \sim N(0, \gamma), u_i \perp v_{Si}, u_i \perp v_{Ti}; (v_{Si}, v_{Ti})^T \sim \mathcal{N}(0, \Sigma_v)
$$

with

$$\Sigma_v = \left(\begin{array}{cc} \sigma^2_{v_S} & \sigma_{v_{ST}} \\ \sigma_{v_{ST}} & \sigma^2_{v_T} \end{array} \right)$$

In this model, $\lambda_{0S}(t)$ is the baseline hazard function associated with the surrogate endpoint and β_S the fixed effects (or log-hazard ratio) corresponding to the covariates $\mathbf{Z}_{S,ij}$; $\lambda_{0T}(t)$ is the baseline hazard function associated with the true endpoint and β_T the fixed effects corresponding to the covariates $\mathbf{Z}_{T,ij}$. The copula model serves to consider dependence between the surrogate and true endpoints at the individual level. In the copula model, θ is the copula parameter used to quantify the strength of association. u_i is a shared frailty effect associated with the baseline hazard function that serve to take into account the heterogeneity between trials of the baseline hazard function, associated with the fact that we have several trials in this meta-analytical design. The power parameter α distinguishes trial-level heterogeneity between the surrogate and the true endpoint. v_{S_i} and v_{T_i} are two correlated random effects treatment-by-trial interactions. Z_{Sij1} or Z_{Tij1} represents the treatment arm to which the patient has been randomized.

For simplicity, we focus on the Clayton and Gumbel-Hougaard copula functions. In Clayton's model, the copula function has the form

$$\varphi_\theta(s) = (1 + \theta s)^{-1/\theta}, \quad \theta > 0$$

and in Gumbel's model, the copula function has the form

$$\varphi_\theta(s) = \exp\left[-s^{1/(1+\theta)}\right], \quad \theta \geq 0$$

Surrogacy evaluation

We proposed to base validation of a candidate surrogate endpoint on Kendall's τ at the individual level and coefficient of determination at the trial level, as in the classical approach (Burzykowski et al., 2001). The formulations are given below.

Individual-level surrogacy

From the proposed model, according to the copula function, it can be shown that Kendall's τ is defined as:

$\tau = \frac{\theta}{\theta+2}$ for Clayton copula and $\tau = \frac{\theta}{\theta+1}$ for Gumbel copula.

where θ is the copula parameter. Kendall's τ is the difference between the probability of concordance and the probability of discordance of two realizations of S_{ij} and T_{ij}. It belongs to the interval [-1,1] and assumes a zero value when S_{ij} and T_{ij} are independent.

Trial-level surrogacy

The key motivation for validating a surrogate endpoint is to be able to predict the effect of treatment on the true endpoint, based on the observed effect of treatment on the surrogate endpoint. As shown by Buyse *et al.* (2000), the coefficenient of determination obtains from the covariance matrix Σ_v of the random effects treatment-by-trial interaction can be used to evaluate underlined prediction, and therefore as surrogacy evaluation measurement at trial-level. It is defined by:

$$R^2_{trial} = \frac{\sigma^2_{v_{ST}}}{\sigma^2_{v_S}\sigma^2_{v_T}}$$

The SEs of R^2_{trial} and τ are calculated using the Delta-method. We also propose R^2_{trial} and 95% CI computed using the parametric bootstrap. The use of delta-method can lead to confidence limits violating the [0,1], as noted by (Burzykowski *et al.*, 2001). However, using other methods would not significantly alter the findings of the surrogacy assessment

Usage

```
jointSurroCopPenal(data, maxit = 40, indicator.alpha = 1,
    frail.base = 1, n.knots = 6, LIMparam = 0.001, LIMlogl = 0.001,
    LIMderiv = 0.001, nb.mc = 1000, nb.gh = 20, nb.gh2 = 32,
    adaptatif = 0, int.method = 0, nb.iterPGH = 5, true.init.val = 0,

    sigma.st.init = 0.48, gamma.init = 0.5, alpha.init = 1,
    betas.init = 0.5, betat.init = 0.5, scale = 1,
    random.generator = 1, kappa.use = 4, random = 0,
    random.nb.sim = 0, seed = 0, init.kappa = NULL, ckappa = c(0,0),
    typecopula = 1, nb.decimal = 4, print.times = TRUE, print.iter = FALSE)
```

Arguments

data   A [data.frame](#) containing at least seven variables entitled:

- patientID: A numeric, that represents the patient's identifier and must be unique;
- trialID: A numeric, that represents the trial in which each patient was randomized;
- timeS: The follow-up time associated with the surrogate endpoint;
- statusS: The event indicator associated with the surrogate endpoint. Normally 0 = no event, 1 = event;
- timeT: The follow-up time associated with the true endpoint;
- statusT: The event indicator associated with the true endpoint. Normally 0 = no event, 1 = event;
- trt: The treatment indicator for each patient, with 1 = treated, 0 = untreated.

maxit   maximum number of iterations for the Marquardt algorithm. The default being 40.

indicator.alpha

A binary, indicating whether the power's parameter α should be estimated (1) or not (0). If 0, α will be set to 1 during estimation. The default is 1.

frail.base   A binary, indicating whether the heterogeneity between trial on the baseline risk is considered (1) or not (0), using the shared cluster specific frailties (u_i). The default is 1.

n.knots   integer giving the number of knots to use. Value required in the penalized likelihood estimation. It corresponds to the (n.knots+2) splines functions for the approximation of the hazard or the survival functions. We estimate I or M-splines of order 4. When the user set a number of knots equals to k (n.knots=k) then the number of interior knots is (k-2) and the number of splines is (k-2)+order. Number of knots must be between 4 and 20. (See [frailtyPenal](#) for more details).

LIMparam	Convergence threshold of the Marquardt algorithm for the parameters, 10^{-3} by default (See `frailtyPenal` for more details).
LIMlogl	Convergence threshold of the Marquardt algorithm for the log-likelihood, 10^{-3} by default (See `frailtyPenal` for more details).
LIMderiv	Convergence threshold of the Marquardt algorithm for the gradient, 10^{-3} by default (See `frailtyPenal` for more details).
nb.mc	Number of samples considered in the Monte-Carlo integration. Required in the event `int.method` is equals to `0`, `2` or `4`. A value between 500 and 1000 most often gives good results. The default is `1000`.
nb.gh	Number of nodes for the Gaussian-Hermite quadrature. It can be chosen among 5, 7, 9, 12, 15, 20 and 32. The default is `20`. A value greater than or equals to `15` allowed good results in simulation studies
nb.gh2	Number of nodes for the Gauss-Hermite quadrature used to re-estimate the model, in the event of non-convergence, defined as previously. The default is `32`.
adaptatif	A binary, indicates whether the pseudo adaptive Gaussian-Hermite quadrature (`1`) or the classical Gaussian-Hermite quadrature (`0`) is used. The default is `0`.
int.method	A numeric, indicates the integration method: `0` for Monte carlo, `1` for Gaussian-Hermite quadrature, `3` for Laplace approximation. The default is `0`.
nb.iterPGH	Number of iterations before the re-estimation of the posterior random effects, in the event of the two-steps pseudo-adaptive Gaussian-hermite quadrature. If set to `0` there is no re-estimation". The default is 5.
true.init.val	Numerical value. Indicates if the given initial values to parameters (`0`) should be considered. If set to `2`, α and γ are initialised using two separed shared frailty model (see `frailtyPenal` for more details);
	$\sigma_{v_S}^2$, $\sigma_{v_T}^2$ and $\sigma_{v_{ST}}$ are fixed by the user or the default values; θ, β_S and β_T are initialized using a classical joint frailty model, considering individual level random effects, with θ the variance of individual level random effects. If the joint frailty model is faced to convergence issues, β_S and β_T are initialized using two shared frailty models. In all other scenarios, if the simplified model does not converge, default given parameters values are used. Initial values for spline's associated parameters are fixed to `0.5`. The default for this argument is `0`.
thetacopula.init	
	Initial values for the copula parameter (θ), required if `true.init.val` is set to `0` or `2`. The default is 1.
sigma.ss.init	Initial values for $\sigma_{v_S}^2$, required if `true.init.val` is set to `0` or `2`. The default is `0.5`.
sigma.tt.init	Initial values for $\sigma_{v_T}^2$, required if `true.init.val` is set to `0` or `2`. The default is `0.5`.
sigma.st.init	Initial values for $\sigma_{v_{ST}}$, required if `true.init.val` is set to `0` or `2`. The default is `0.48`.
gamma.init	Initial values for γ, required if `true.init.val` is set to `0` or `2`. The default is `0.5`.

alpha.init	Initial values for α, required if `true.init.val` is set to 0 or 2. The default is 1.
betas.init	Initial values for β_S , required if `true.init.val` is set to 0 or 2. The default is 0.5.
betat.init	Initial values for β_T , required if `true.init.val` is set to 0 or 2. The default is 0.5.
scale	A numeric that allows to rescale (by multiplication) the survival times, to avoid numerical problems in the event of some convergence issues. If no change is needed the argument is set to 1, the default value. eg: 1/365 aims to convert days to years ".
random.generator	
	Random number generator used by the Fortran compiler, 1 for the intrinsec subroutine Random_number and 2 for the subroutine `uniran()`. The default is 1. In the event of convergence problem with `int.method` set to 0, 2 or 4, that requires integration by Monte-Carlo, user could change the random numbers generator.
kappa.use	A numeric, that indicates how to manage the smoothing parameters k_1 and k_2 in the event of convergence issues. If it is set to 1, the given smoothing parameters or those obtained by cross-validation are used. If it is set to 3, the associated smoothing parameters are successively divided by 10, in the event of convergence issues until 5 times. If it is set to 4, the management of the smoothing parameter is as in the event 1, follows by the successive division as described in the event 3 and preceded by the changing of the number of nodes for the Gauss-Hermite quadrature. The default is 4.
random	A binary that says if we reset the random number generation with a different environment at each call (1) or not (0). If it is set to 1, we use the computer clock as seed. In the last case, it is not possible to reproduce the generated datasets". The default is 0. Required if `random.generator` is set to 1.
random.nb.sim	If `random` is set to 1, a binary that indicates the number of generations that will be made.
seed	The seed to use for data (or samples) generation. required if `random` is set to 0. The default is 0.
init.kappa	smoothing parameter used to penalized the log-likelihood. By default (init.kappa = NULL) the values used are obtain by cross-validation.
ckappa	Vector of two fixed values to add to the smoothing parameters. By default it is set to (0,0). this argument allows to well manage the smoothing parameters in the event of convergence issues.
typecopula	The copula function used, can be 1 for clayton or 2 for Gumbel-Hougaard. The default is 1
nb.decimal	Number of decimal required for results presentation.
print.times	a logical parameter to print estimation time. Default is TRUE.
print.iter	a logical parameter to print iteration process. Default is FALSE.

Details

The estimated parameter are obtained using the robust Marquardt algorithm (Marquardt, 1963) which is a combination between a Newton-Raphson algorithm and a steepest descent algorithm.

The iterations are stopped when the difference between two consecutive log-likelihoods was small ($< 10^{-3}$), the estimated coefficients were stable (consecutive values ($< 10^{-3}$)), and the gradient small enough ($< 10^{-3}$), by default. Cubic M-splines of order 4 are used for the hazard function, and I-splines (integrated M-splines) are used for the cumulative hazard function.

The inverse of the Hessian matrix is the variance estimator and to deal with the positivity constraint of the variance component and the spline coefficients, a squared transformation is used and the standard errors are computed by the Δ-method (Knight & Xekalaki, 2000). The smooth parameter can be chosen by maximizing a likelihood cross validation criterion (Joly and other, 1998).

We proposed based on the joint surrogate model a new definition of the Kendall's τ. Moreover, distinct numerical integration methods are available to approximate the integrals in the marginal log-likelihood.

Non-convergence case management procedure

Special attention must be given to initializing model parameters, the choice of the number of spline knots, the smoothing parameters and the number of quadrature points to solve convergence issues. We first initialized parameters using the user's desired strategy, as specified by the option `true.init.val`. When numerical or convergence problems are encountered, with `kappa.use` set to 4, the model is fitted again using a combination of the following strategies: vary the number of quadrature point (`nb.gh` to `nb.gh2` or `nb.gh2` to `nb.gh`) in the event of the use of the Gaussian Hermite quadrature integration (see `int.method`); divided or multiplied the smoothing parameters (`k_1` , `k_2`) by 10 or 100 according to their preceding values, or used parameter vectors obtained during the last iteration (with a modification of the number of quadrature points and smoothing parameters). Using this strategy, we usually obtained during simulation the rejection rate less than 3%. A sensitivity analysis was conducted without this strategy, and similar results were obtained on the converged samples, with about a 23% rejection rate.

Value

This function return an object of class jointSurroPenal with elements :

EPS
: A vector containing the obtained convergence thresholds with the Marquardt algorithm, for the parameters, the log-likelihood and for the gradient;

b
: A vector containing estimates for the splines parameter's; elements of the lower triangular matrix (L) from the Cholesky decomposition such that $\Sigma = LL^T$, with Σ the covariance of the random effects (v_{S_i}, v_{T_i}); the coefficient α (if `indicator.alpha` is set to 1); the satandard error of the random effect u_i; the logarithm of the copula parameter (θ) if the Clayton copula function is considered, or the squared root of θ if the Gumbel copula is considered. The last two parameters represent the regression coefficients β_S and β_T;

varH
: The variance matrix of all parameters in b (before positivity constraint transformation for the variance of the measurement error, for which the delta method is used);

varHIH
: The robust estimation of the variance matrix of all parameters in b;

loglikPenal
: The complete marginal penalized log-likelihood;

LCV
: the approximated likelihood cross-validation criterion in the semiparametric case (with H minus the converged Hessian matrix, and l(.) the full log-likelihood).

$$LCV = \frac{1}{n}(trace(H_{pl}^{-1}H) - l(.))$$

;

xS	vector of times for surrogate endpoint where both survival and hazard function are estimated. By default seq(0,max(time),length=99), where time is the vector of survival times;
lamS	array (dim = 3) of hazard estimates and confidence bands, for surrogate endpoint;
survS	array (dim = 3) of baseline survival estimates and confidence bands, for surrogate endpoint;
xT	vector of times for true endpoint where both survival and hazard function are estimated. By default seq(0, max(time), length = 99), where time is the vector of survival times;
lamT	array (dim = 3) of hazard estimates and confidence bands, for true endpoint;
survT	array (dim = 3) of baseline survival estimates and confidence bands, for true endpoint;
n.iter	number of iterations needed to converge;
theta	Estimate for θ;
gamma	Estimate for γ;
alpha	Estimate for α;
zeta	A value equals to 1, no really use in this function;
sigma.s	Estimate for $\sigma_{v_S}^2$;
sigma.t	Estimate for $\sigma_{v_T}^2$;
sigma.st	Estimate for $\sigma_{v_{ST}}$;
beta.s	Estimate for β_S ;
beta.t	Estimate for β_T ;
ui	A binary, that indicates if the heterogeneity between trial on the baseline risk has been Considered (1), using the shared cluster specific frailties (u_i) , or not (0);
ktau	The Kendall's τ with the correspondant 95 % CI obtained from the delta-method;
R2.boot	The R_{trial}^2 with the correspondant 95 % CI obtained from the parametric bootstrap;
Coefficients	The estimates with the corresponding standard errors and the 95 % CI
kappa	Positive smoothing parameters used for convergence. These values could be different to initial values if kappa.use is set to 3 or 4;
scale	The value used to rescale the survival times
data	The dataset used in the model
varcov.Sigma	Covariance matrix of the estimates of ($\sigma_{v_S}^2$,$\sigma_{v_T}^2$,$\sigma_{v_{ST}}$) obtained from the delta-method
parameter	List of all arguments used in the model
type.joint	A code 3 that represents the joint frailty-copula model. This output is used in other functions

jointSurroPenal | *Fit the one-step Joint surrogate model for evaluating a canditate surrogate endpoint*

Description

Joint Frailty Surrogate model definition

Fit the one-step Joint surrogate model for the evaluation of a canditate surrogate endpoint, with different integration methods on the random effects, using a semiparametric penalized likelihood estimation. This approach extends that of Burzykowski et al. (2001) by including in the same joint frailty model the individual-level and the trial-level random effects. This function can also be used for mediation analysis where a direct effect of the surrogate time S on the final endpoint T is allowed through a function $g(S)$. For the jth subject (j=1, ..., n_i) of the ith trial i (i=1, ..., G), the joint surrogate model is defined as follows:

$$\begin{cases} \lambda_{S,ij}(t|\omega_{ij}, u_i, v_{S_i}, Z_{ij1}) &= \lambda_{0S}(t)\exp(\omega_{ij} + u_i + v_{S_i}Z_{ij1} + \beta_S Z_{ij1}) \\ \lambda_{T,ij}(t|\omega_{ij}, u_i, v_{T_i}, Z_{ij1}) &= \lambda_{0T}(t)\exp(\zeta\omega_{ij} + \alpha u_i + v_{T_i}Z_{ij1} + \beta_T Z_{ij1}) \end{cases}$$

where,

$$\omega_{ij} \sim N(0, \theta), u_i \sim N(0, \gamma), \omega_{ij} \perp u_i, u_i \perp v_{S_i}, u_i \perp v_{T_i}$$

and $(v_{S_i}, v_{T_i})^T \sim \mathcal{N}(0, \Sigma_v)$, with

$$\Sigma_v = \begin{pmatrix} \sigma_{v_S}^2 & \sigma_{v_{ST}} \\ \sigma_{v_{ST}} & \sigma_{v_T}^2 \end{pmatrix}$$

In this model, $\lambda_{0S}(t)$ is the baseline hazard function associated with the surrogate endpoint and β_S the fixed treatment effect (or log-hazard ratio); $\lambda_{0T}(t)$ is the baseline hazard function associated with the true endpoint and β_T the fixed treatment effect. ω_{ij} is a shared individual-level frailty that serve to take into account the heterogeneity in the data at the individual level; u_i is a shared frailty effect associated with the baseline hazard function that serve to take into account the heterogeneity between trials of the baseline hazard function, associated with the fact that we have several trials in this meta-analytical design. The power parameters ζ and α distinguish both individual and trial-level heterogeneities between the surrogate and the true endpoint. v_{S_i} and v_{T_i} are two correlated random effects treatment-by-trial interactions. Z_{ij1} represents the treatment arm to which the patient has been randomized. In the mediation analysis setting, the hazard function for the true endpoint becomes:

$$\lambda_{T,ij}(t|\omega_{ij}, u_i, v_{T_i}, Z_{ij1}, S_{ij}) = \lambda_{0T}(t)\exp(\zeta\omega_{ij} + \alpha u_i + v_{T_i}Z_{ij1} + \beta_T Z_{ij1} + I(S_{ij} \leq t)g(S_{ij}))$$

where the term $I(S \leq t)g(S)$ allows for a direct effect of the surrogate time S on the risk of occurrence of the final endpoint T.

Surrogacy evaluation

We proposed new definitions of Kendall's τ and coefficient of determination as individual-level and trial-level association measurements, to evaluate a candidate surrogate endpoint (Sofeu *et al.*,

2018). For the surrogacy in the mediation analysis setting see the "Surrogacy through mediation" Section.

Individual-level surrogacy

To measure the strength of association between S_{ij} and T_{ij} after adjusting the marginal distributions for the trial and the treatment effects, as show in Sofeu *et al.*(2018), we use the Kendall's τ define by :

$$
\begin{aligned}
\tau \quad &= 2 \int_{u_i} \int_{\omega_{ij}} \int_{u_{i'}} \int_{\omega_{i'j'}} \{ \\
&\frac{\exp(\omega_{ij}+u_i+\zeta\omega_{ij}+\alpha u_i)+\exp(\omega_{i'j'}+u_{i'}+\zeta\omega_{i'j'}+\alpha u_{i'})}{(\exp(\omega_{i'j'}+u_{i'})+\exp(\omega_{ij}+u_i))(\exp(\zeta\omega_{i'j'}+\alpha u_{i'})+\exp(\zeta\omega_{ij}+\alpha u_i))} \\
&\frac{1}{\sqrt{2\pi\theta}} \exp\left[-\frac{1}{2}\frac{\omega_{i'j'}^2}{\theta}\right] \frac{1}{\sqrt{2\pi\gamma}} \exp\left[-\frac{1}{2}\frac{u_{i'}^2}{\gamma}\right] d\omega_{i'j'} du_{i'} \\
&\frac{1}{\sqrt{2\pi\theta}} \exp\left[-\frac{1}{2}\frac{\omega_{ij}^2}{\theta}\right] \frac{1}{\sqrt{2\pi\gamma}} \exp\left[-\frac{1}{2}\frac{u_i^2}{\gamma}\right] d\omega_{ij} du_i \} - 1
\end{aligned}
$$

where θ, ζ, α and γ are estimated using the joint surrogate model defined previously. Kendall's τ is the difference between the probability of concordance and the probability of discordance of two realizations of S_{ij} and T_{ij}. It belongs to the interval [-1,1] and assumes a zero value when S_{ij} and T_{ij} are independent. We estimate Kendall's τ using Monte-Carlo or Gaussian Hermite quadrature integration methods. Its confidence interval is estimated using parametric bootstrap

Trial-level surrogacy

The key motivation for validating a surrogate endpoint is to be able to predict the effect of treatment on the true endpoint, based on the observed effect of treatment on the surrogate endpoint. As shown by Buyse *et al.* (2000), the coeffcienent of determination obtains from the covariance matrix Σ_v of the random effects treatment-by-trial interaction can be used to evaluate underlined prediction, and therefore as surrogacy evaluation measurement at trial-level. It is defined by:

$$
R_{trial}^2 = \frac{\sigma_{v_{ST}}^2}{\sigma_{v_S}^2 \sigma_{v_T}^2}
$$

The SEs of R_{trial}^2 is calculated using the Delta-method. We also propose R_{trial}^2 and 95% CI computed using the parametric bootstrap. The use of delta-method can lead to confidence limits violating the [0,1], as noted by (Burzykowski *et al.*, 2001). However, using other methods would not significantly alter the findings of the surrogacy assessment

Surrogacy through mediation

In the mediation analysis setting, the surrogacy measure is the proportion of treatment effect on the final endpoint T that goes through its effect on the surrogate S. This measure is a time-dependent function $R(t)$ defined as:

$$
R(t) = \frac{S_{11}(t) - S_{10}(t)}{S_{11}(t) - S_{00}(t)} = \frac{NIE(t)}{TE(t)}
$$

where NIE and TE stand for "natual indirect effect" and "total effect" respectively. The numerator is the difference of the survival function of T for a subject whose treatment has been set to 1 (experimental arm) for both S and T versus a subject for which the treatment for T is still 1 but is set 0 for S. This corresponds to the indirect effect (in ther of survival probability) of the treatment on T through S. The denominator is the total effect of the treatment on T.

```

Arguments

data   A [data.frame](#) containing at least seven variables entitled:

- patientID: A numeric, that represents the patient's identifier and must be unique;
- trialID: A numeric, that represents the trial in which each patient was randomized;
- timeS: The follow-up time associated with the surrogate endpoint;
- statusS: The event indicator associated with the surrogate endpoint. Normally 0 = no event, 1 = event;
- timeT: The follow-up time associated with the true endpoint;
- statusT: The event indicator associated with the true endpoint. Normally 0 = no event, 1 = event;
- trt: The treatment indicator for each patient, with 1 = treated, 0 = untreated.

maxit   maximum number of iterations for the Marquardt algorithm. The default being 40.

indicator.zeta A binary, indicates whether the power's parameter ζ should be estimated (1) or not (0). If 0, ζ will be set to 1 during estimation. The default is 1. This parameter can be set to 0 in the event of convergence and identification issues.

indicator.alpha

                A binary, indicating whether the power's parameter α should be estimated (1) or not (0). If 0, α will be set to 1 during estimation. The default is 1.

frail.base   A binary, indicating whether the heterogeneity between trial on the baseline risk is considered (1) or not (0), using the shared cluster specific frailties (u_i). The default is 1.

n.knots   integer giving the number of knots to use. Value required in the penalized likelihood estimation. It corresponds to the (n.knots+2) splines functions for the approximation of the hazard or the survival functions. We estimate I or M-splines of order 4. When the user set a number of knots equals to k (n.knots=k) then the

	number of interior knots is (k-2) and the number of splines is (k-2)+order. Number of knots must be between 4 and 20. (See [frailtyPenal](#) for more details).
LIMparam	Convergence threshold of the Marquardt algorithm for the parameters, 10^{-3} by default (See [frailtyPenal](#) for more details).
LIMlogl	Convergence threshold of the Marquardt algorithm for the log-likelihood, 10^{-3} by default (See [frailtyPenal](#) for more details).
LIMderiv	Convergence threshold of the Marquardt algorithm for the gradient, 10^{-3} by default (See [frailtyPenal](#) for more details).
nb.mc	Number of samples considered in the Monte-Carlo integration. Required in the event int.method is equals to 0, 2 or 4. A value between 100 and 300 most often gives good results. However, beyond 300, the program takes a lot of time to estimate the parameters. The default is 300.
nb.gh	Number of nodes for the Gaussian-Hermite quadrature. It can be chosen among 5, 7, 9, 12, 15, 20 and 32. The default is 32.
nb.gh2	Number of nodes for the Gauss-Hermite quadrature used to re-estimate the model, in the event of non-convergence, defined as previously. The default is 20.
adaptatif	A binary, indicates whether the pseudo adaptive Gaussian-Hermite quadrature (1) or the classical Gaussian-Hermite quadrature (0) is used. The default is 0.
int.method	A numeric, indicates the integration method: 0 for Monte carlo, 1 for Gaussian-Hermite quadrature, 2 for a combination of both Gaussian-Hermite quadrature to integrate over the individual-level random effects and Monte carlo to integrate over the trial-level random effects, 4 for a combination of both Monte carlo to integrate over the individual-level random effects and Gaussian-Hermite quadrature to integrate over the trial-level random effects. The default is 2.
nb.iterPGH	Number of iterations before the re-estimation of the posterior random effects, in the event of the two-steps pseudo-adaptive Gaussian-hermite quadrature. If set to 0 there is no re-estimation". The default is 5.
nb.MC.kendall	Number of generated points used with the Monte-Carlo to estimate integrals in the Kendall's τ formulation. Beter to use at least 4000 points for stable reseults. The default is 10000.
nboot.kendall	Number of samples considered in the parametric bootstrap to estimate the confidence interval of the Kendall's τ. The default is 1000.
true.init.val	Numerical value. Indicates if the given initial values to parameters (0) should be considered. If set to 2, α and γ are initialised using two separed shared frailty model (see [frailtyPenal](#) for more details); $\sigma^2_{v_S}$, $\sigma^2_{v_T}$ and $\sigma_{v_{ST}}$ are fixed by the user or the default values; ζ, θ, β_S and β_T are initialized using a classical joint frailty model, considering individual level random effects. If the joint frailty model is faced to convergence issues, β_S and β_T are initialized using two shared frailty models. In all other scenarios, if the simplified model does not converge, default given parameters values are used. Initial values for spline's associated parameters are fixed to 0.5. The default for this argument is 0.
theta.init	Initial values for θ, required if true.init.val is set to 0 or 2. The default is 1.
sigma.ss.init	Initial values for $\sigma^2_{v_S}$, required if true.init.val is set to 0 or 2. The default is 0.5.

sigma.tt.init	Initial values for $\sigma^2_{v_T}$, required if `true.init.val` is set to 0 or 2. The default is 0.5.
sigma.st.init	Initial values for $\sigma_{v_{ST}}$, required if `true.init.val` is set to 0 or 2. The default is 0.48.
gamma.init	Initial values for γ, required if `true.init.val` is set to 0 or 2. The default is 0.5.
alpha.init	Initial values for α, required if `true.init.val` is set to 0 or 2. The default is 1.
zeta.init	Initial values for ζ, required if `true.init.val` is set to 0 or 2. The default is 1.
betas.init	Initial values for β_S, required if `true.init.val` is set to 0 or 2. The default is 0.5.
betat.init	Initial values for β_T, required if `true.init.val` is set to 0 or 2. The default is 0.5.
scale	A numeric that allows to rescale (multiplication) the survival times, to avoid numerical problems in the event of some convergence issues. If no change is needed the argument is set to 1, the default value. eg: code1/365 aims to convert days to years ".
random.generator	
	Random number generator used by the Fortran compiler, 1 for the intrinsec subroutine Random_number and 2 for the subroutine `uniran()`. The default is 1. in the event of convergence problem with `int.method` set to 0, 2 or 4, that requires integration by Monte-Carlo, user could change the random numbers generator.
kappa.use	A numeric, that indicates how to manage the smoothing parameters k_1 and k_2 in the event of convergence issues. If it is set to 1, the given smoothing parameters or those obtained by cross-validation are used. If it is set to 3, the associated smoothing parameters are successively divided by 10, in the event of convergence issues until 5 times. If it is set to 4, the management of the smoothing parameter is as in the event 1, follows by the successive division as described in the event 3 and preceded by the changing of the number of nodes for the Gauss-Hermite quadrature. The default is 4.
random	A binary that says if we reset the random number generation with a different environment at each call (1) or not (0). If it is set to 1, we use the computer clock as seed. In the last case, it is not possible to reproduce the generated datasets. The default is 0. Required if `random.generator` is set to 1.
random.nb.sim	If `random` is set to 1, a binary that indicates the number of generations that will be made.
seed	The seed to use for data (or samples) generation. required if `random` is set to 0. The default is 0.
init.kappa	smoothing parameter used to penalized the log-likelihood. By default (init.kappa = NULL) the values used are obtain by cross-validation.
ckappa	Vector of two fixed values to add to the smoothing parameters. By default it is set to (0,0). this argument allows to well manage the smoothing parameters in the event of convergence issues.
nb.decimal	Number of decimal required for results presentation.
print.times	a logical parameter to print estimation time. Default is TRUE.

print.iter	a logical parameter to print iteration process. Default is FALSE.
mediation	a logical value indicating if the mediation analysis method is used. Default is FALSE.
g.nknots	In the case of a mediation analysis, indicates how many inner knots are used in the splines basis for estimating the function $g(s)$. The value of g.nknots should be between 1 and 5. Default is 1.
rt.times	In the mediation analysis setting, a vector of times for which the funtion $R(t)$ is evaluated. Specified time points must be in the range of the observed event times. The length of the vector should be less than 200.
rt.ntimes	In the mediation setting, if the argument rt.times is not specified the argument rt.ntimes allows the user to only specify a number of time points for which the function $R(t)$ has to be computed. This argument is only to be used if rt.times is not specified. In that case the default value for rt.ntimes is 10. The value of rt.ntimes should be less than 200.
rt.nmc	An integer indicating how many Monte Carlo simulations are used to integrate over the random effects in the computation of the function $R(t)$. in the mediation analysis setting. Default is 500.
rt.boot	A logical value indicating if bootstrapped confidence bands needs to be computed for the function $R(t)$ in the mediation analysis setting. Default is FALSE.
rt.nboot	An integer indicating how many bootstrapped replicates of R(t) needs to be computed to derive confidence bands for R(t). Default is 2000.
rt.boot.nmc	If rt.boot is TRUE, indicates how many Monte Carlo simulations are used to integrate over the random effects in the bootstrapped functions $R(t)$ in the mediation analysis setting. Default is 500
rt.integ.type	An integer indicating which type of integration over the distribution of S should be used in the computation of the function $R(t)$. If set to 1, a simple trapezoidal rule is used with 300 integration points. If set to 2 a Gauss-Laguerre quadrature is used with 30 knots. Default is 2.

Details

The estimated parameter are obtained using the robust Marquardt algorithm (Marquardt, 1963) which is a combination between a Newton-Raphson algorithm and a steepest descent algorithm. The iterations are stopped when the difference between two consecutive log-likelihoods was small ($< 10^{-3}$), the estimated coefficients were stable (consecutive values ($< 10^{-3}$)), and the gradient small enough ($< 10^{-3}$), by default. Cubic M-splines of order 4 are used for the hazard function, and I-splines (integrated M-splines) are used for the cumulative hazard function.

The inverse of the Hessian matrix is the variance estimator and to deal with the positivity constraint of the variance component and the spline coefficients, a squared transformation is used and the standard errors are computed by the Δ-method (Knight & Xekalaki, 2000). The smooth parameter can be chosen by maximizing a likelihood cross validation criterion (Joly and other, 1998).

We proposed based on the joint surrogate model a new definition of the Kendall's τ. Moreover, distinct numerical integration methods are available to approximate the integrals in the marginal log-likelihood.

Non-convergence case management procedure

Special attention must be given to initializing model parameters, the choice of the number of spline knots, the smoothing parameters and the number of quadrature points to solve convergence issues. We first initialized parameters using the user's desired strategy, as specified by the option `true.init.val`. When numerical or convergence problems are encountered, with `kappa.use` set to 4, the model is fitted again using a combination of the following strategies: vary the number of quadrature point (`nb.gh` to `nb.gh2` or `nb.gh2` to `nb.gh`) in the event of the use of the Gaussian Hermite quadrature integration (see `int.method`); divided or multiplied the smoothing parameters (k_1 , k_2) by 10 or 100 according to their preceding values, or used parameter vectors obtained during the last iteration (with a modification of the number of quadrature points and smoothing parameters). Using this strategy, we usually obtained during simulation the rejection rate less than 3%. A sensitivity analysis was conducted without this strategy, and similar results were obtained on the converged samples, with about a 23% rejection rate.

Value

This function return an object of class jointSurroPenal or jointSurroMed in the mediation analysis setting with elements:

EPS   A vector containing the obtained convergence thresholds with the Marquardt algorithm, for the parameters, the log-likelihood and for the gradient;

b   A vector containing estimates for the splines parameter's; the power's parameter ζ (if `indicator.zeta` is set to 1), the standard error of the shared individual-level frailty ω_{ij} (θ),elements of the lower triangular matrix (L) from the Cholesky decomposition such that $\Sigma = LL^T$, with Σ the covariance of the random effects (v_{S_i}, v_{T_i}); the coefficient α (if `indicator.alpha` is set to 1); the satandard error of the random effect u_i; and the regression coefficients β_S and β_T;

varH   The variance matrix of all parameters in b (before positivity constraint transformation for the variance of the measurement error, for which the delta method is used);

varHIH   The robust estimation of the variance matrix of all parameters in b;

loglikPenal   The complete marginal penalized log-likelihood;

LCV   the approximated likelihood cross-validation criterion in the semiparametric case (with H minus the converged Hessian matrix, and l(.) the full log-likelihood).

$$LCV = \frac{1}{n}(trace(H_{pl}^{-1}H) - l(.))$$

;

xS   vector of times for surrogate endpoint where both survirt.nmc.bootval and hazard function are estimated. By default seq(0,max(time),length=99), where time is the vector of survival times;

lamS   array (dim = 3) of hazard estimates and confidence bands, for surrogate endpoint;

survS   array (dim = 3) of baseline survival estimates and confidence bands, for surrogate endpoint;

xT   vector of times for true endpoint where both survival and hazard function are estimated. By default seq(0, max(time), length = 99), where time is the vector of survival times;

`lamT`	array (dim = 3) of hazard estimates and confidence bands, for true endpoint;
`survT`	array (dim = 3) of baseline survival estimates and confidence bands, for true endpoint;
`n.iter`	number of iterations needed to converge;
`theta`	Estimate for θ;
`gamma`	Estimate for γ;
`alpha`	Estimate for α;
`zeta`	Estimate for ζ;
`sigma.s`	Estimate for $\sigma_{v_S}^2$;
`sigma.t`	Estimate for $\sigma_{v_T}^2$;
`sigma.st`	Estimate for $\sigma_{v_{ST}}$;
`beta.s`	Estimate for β_S ;
`beta.t`	Estimate for β_T ;
`ui`	A binary, that indicates if the heterogeneity between trial on the baseline risk has been Considered (1), using the shared cluster specific frailties (u_i) , or not (0);
`ktau`	The Kendall's τ with the correspondant 95 % CI computed using the parametric bootstrap;
`R2.boot`	The R_{trial}^2 with the correspondant 95 % CI computed using the parametric bootstrap;
`Coefficients`	The estimates with the corresponding standard errors and the 95 % CI
`kappa`	Positive smoothing parameters used for convergence. These values could be different to initial values if `kappa.use` is set to 3 or 4;
`scale`	The value used to rescale the survival times
`data`	The dataset used in the model
`varcov.Sigma`	covariance matrix of ($\sigma_{v_S}^2$,$\sigma_{v_T}^2$,$\sigma_{v_{ST}}$) obtained from the delta-method
`parameter`	list of all arguments used in the model
`mediation`	List returned in the case where the option `mediation` is set to `TRUE` which contains:

- data.rt: A dataframe containing estimated values for the funtion R(t) and the natural effects for differents time points
- g.knots: The vector of knots used in the spline basis for the function g.
- g.order: The order of the spline basis used to estimate the function g.
- g.coefficients: A vector containing the estimated coefficients associated with the splines in the estimation of the function g.
- data.g: A dataframe containing the values of the estimated function g computed at several time points and the associated 95
- Rt.ci: A dataframe containing the 95
- TE.ci: A dataframe containing the 95
- NDE.ci: A dataframe containing the 95
- NIE.ci: A dataframe containing the 95

# Mediation analysis on the adjuvant chemotherapy
# dataset where the surrogate is a time-to-relapse and the final endpoint is death.
# 4 knots are used to estimate the two baseline hazard functions.
# The function g(s) is estimated using cubic b-splines with 1 interior
# knot ('g.nkots=1'). The function R(t) is computed at 100 time points
# using 10.000 Monte Carlo simulations for integration over the random effects.
# To reduce computation time in the provided example only one fifth of the
# the original dataset is used and the confidence bands for the function
# R(t) are not computed as well as the power parameters associated with
# the random effects. Full example is commented thereafter.

# We first need to change the variable "statusS" which in the dataset
# encodes the indicator of a disease free survival event to an indicator
# of a time to relapse event (i.e., resurgence of cancer or
# onset of a second cancer) that excludes death as a composite event.
# Thus, the patients whose variables "timeS" and "timeT" are equal
# and whose variable "statusS" is equal to 1 will have
# "statuS" be set to 0. We do this because composite endpoint may not
# be appropriate in the setting of mediation analysis.

jointSurroPenalSimul   *Simulation studies based on the one-step Joint surrogate models for*
the evaluation of a canditate surrogate endpoint

Description

This function aims to allow simulation studies, based on the joint frailty surrogate model, described
in jointSurroPenal. Simulation can also be based on the joint frailty-copula model described in
jointSurroCopPenal

Usage

```
jointSurroPenalSimul(maxit=40, indicator.zeta = 1,
    indicator.alpha = 1, frail.base = 1, n.knots = 6, nb.dataset = 1,
    nbSubSimul=1000, ntrialSimul=30, LIMparam = 0.001,
    LIMlogl = 0.001, LIMderiv = 0.001, nb.mc = 300, nb.gh = 32,
    nb.gh2 = 20, adaptatif = 0, int.method = 2, nb.iterPGH = 5,
    nb.MC.kendall = 10000, nboot.kendall = 1000, true.init.val = 0,
    theta.init = 1, sigma.ss.init = 0.5, sigma.tt.init = 0.5,
    sigma.st.init = 0.48, gamma.init = 0.5, alpha.init = 1,

    mbetast =NULL, mbetast.init = NULL, typecopula =1, theta.copula = 6,
    thetacopula.init = 3, filter.surr = c(1), filter.true = c(1),
    nb.decimal = 4, pfs = 0, print.times = TRUE, print.iter=FALSE)
```

Arguments

maxit	maximum number of iterations for the Marquardt algorithm. Default is 40.
indicator.zeta	A binary, indicates whether the power's parameter ζ should be estimated (1) or not (0). It is required if type.joint.estim = 1. If 0, ζ will be set to 1 during estimation. The default is 1. This parameter can be seted to 0 in the event of identification issues.
indicator.alpha	
	A binary, indicates whether the power's parameter α should be estimated (1) or not (0). If 0, α will be set to 1 during estimation. The default is 1. This parameter can be seted to 0 in the event of identification issues.
frail.base	Considered the heterogeneity between trial on the baseline risk (1), using the shared cluster specific frailties (u_i), or not (0). The default is 1.
n.knots	integer giving the number of knots to use. Value required in the penalized likelihood estimation. It corresponds to the (n.knots+2) splines functions for the approximation of the hazard or the survival functions. We estimate I or M-splines of order 4. When the user set a number of knots equals to k (n.knots=k) then the number of interior knots is (k-2) and the number of splines is (k-2)+order. Number of knots must be between 4 and 20. (See frailtyPenal for more details).
nb.dataset	Number of dataset to analyze. The default is 1.
nbSubSimul	Number of subjects.
ntrialSimul	Number of trials.
LIMparam	Convergence threshold of the Marquardt algorithm for the parameters, 10^{-3} by default (See frailtyPenal for more details).
LIMlogl	Convergence threshold of the Marquardt algorithm for the log-likelihood, 10^{-3} by default (See frailtyPenal for more details).
LIMderiv	Convergence threshold of the Marquardt algorithm for the gradient, 10^{-3} by default (See frailtyPenal for more details).
nb.mc	Number of samples considered in the Monte-Carlo integration. Required in the event int.method is equals to 0, 2 or 4. A value between 100 and 300 most often gives good results. However, beyond 300, the program takes a lot of time to estimate the parameters. The default is 300.
nb.gh	Number of nodes for the Gaussian-Hermite quadrature. It can be chosen among 5, 7, 9, 12, 15, 20 and 32. The default is 32.
nb.gh2	Number of nodes for the Gauss-Hermite quadrature used to re-estimate the model, in the event of non-convergence, defined as previously. The default is 20.
adaptatif	A binary, indicates whether the pseudo adaptive Gaussian-Hermite quadrature (1) or the classical Gaussian-Hermite quadrature (0) is used. The default is 0.
int.method	A numeric, indicates the integration method: 0 for Monte carlo, 1 for Gaussian-Hermite quadrature. If type.joint.estim = 1 this parameter can be set to 2 for a combination of both Gaussian-Hermite quadrature to integrate over the individual-level random effects and Monte carlo to integrate over the trial-level random effects, 4 for a combination of both Monte carlo to integrate over the individual-level random effects and Gaussian-Hermite quadrature to integrate

	over the trial-level random effects. If `type.joint.estim = 3`, value 3 indicates integration using Laplace approximation . The default is 2.
`nb.iterPGH`	Number of iterations before the re-estimation of the posterior random effects, in the event of the two-steps pseudo-adaptive Gaussian-hermite quadrature. If set to `0` there is no re-estimation". The default is 5.
`nb.MC.kendall`	Number of generated points used with the Monte-Carlo to estimate integrals in the Kendall's τ formulation. Beter to use at least 4000 points for stable results. Required if `type.joint.estim = 1`, the default is `10000`.
`nboot.kendall`	Number of samples considered in the parametric bootstrap to estimate the confidence interval of the Kendall's τ, or R^2_{trial}. The default is `1000`.
`true.init.val`	Numerical value. Indicates if the real parameter values (`1`), or the given initial values to parameters (`0`) should be considered. If set to 2, α and γ are initialised using two separed shared frailty model (see [frailtyPenal](#) for more details); $\sigma^2_{v_S}$, $\sigma^2_{v_T}$ and $\sigma_{v_{ST}}$ are fixed using the default initial values given by the user; ζ, θ, β_S and β_T are initialized using a classical joint frailty model, considering individual level random effects. If the joint frailty model is faced to convergence issues, β_S and β_T are initialized using two shared frailty models. In all others scenarios, if the simplified model does not converge, default given parameters values are used. Initial values for spline's associated parameters are fixed to `0.5`. The default for this argument is `0`.
`theta.init`	Initial values for θ, required if `true.init.val` is set to `0` or 2, and `type.joint.estim = 1`. The default is 1.
`sigma.ss.init`	Initial values for $\sigma^2_{v_S}$, required if `true.init.val` is set to `0` or 2. The default is `0.5`.
`sigma.tt.init`	Initial values for $\sigma^2_{v_T}$, required if `true.init.val` is set to `0` or 2. The default is `0.5`.
`sigma.st.init`	Initial values for $\sigma_{v_{ST}}$, required if `true.init.val` is set to `0` or 2. The default is `0.48`.
`gamma.init`	Initial values for γ, required if `true.init.val` is set to `0` or 2. The default is `0.5`.
`alpha.init`	Initial values for α, required if `true.init.val` is set to `0` or 2. The default is 1.
`zeta.init`	Initial values for ζ, required if `true.init.val` is set to `0` or 2 and `type.joint.estim = 1`. The default is 1.
`betas.init`	Initial values for β_S , required if `true.init.val` is set to `0` or 2. The default is `0.5`.
`betat.init`	Initial values for β_T , required if `true.init.val` is set to `0` or 2. The default is `0.5`.
`random.generator`	
	Random number generator used by the Fortran compiler, `1` for the intrinsec subroutine `Random_number` and 2 for the subroutine `uniran()`. The default is 1.
`equi.subj.trial`	
	A binary, that indicates if the same proportion of subjects per trial should be considered in the procces of data generation (1) or not (0). In the event of different trial sizes, fill in `prop.subj.trial` the proportions of subjects to be considered per trial. The default is 1.

prop.subj.trial
    Vector of the proportions of subjects to consider per trial. Requires if the argument equi.subj.trial is different to 1. The size of this vector is equal to the number of trials.

equi.subj.trt   Indicates if the same proportion of treated subjects per trial should be considered (1) or not (0). If 0, fill in prop.subj.trt the proportions of treated subjects to be considered per trial. The default is 1.

prop.subj.trt   Vector of the proportions of treated subjects to consider per trial. Requires if the argument equi.subj.trt is different to 0.5. The size of this vector is equal to the number of trials.

theta2   True value for θ. Require if type.joint.simul = 1, the default is 3.5.

zeta   True value for ζ in the event of simulation. The default is 1.

gamma.ui   True value for γ in the event of simulation. The default is 2.5.

alpha.ui   True value for α in the event of simulation. The default is 1.

betas   True value for β_S in the event of simulation. The default is -1.25.

betat   True value for β_T in the event of simulation. The default is -1.25.

lambdas   Desired scale parameter for the Weibull distribution associated with the Surrogate endpoint. The default is 1.8.

nus   Desired shape parameter for the Weibull distribution associated with the Surrogate endpoint. The default is 0.0045.

lambdat   Desired scale parameter for the Weibull distribution associated with the True endpoint.The default is 3.

nut   Desired shape parameter for the Weibull distribution associated with the True endpoint. The default is 0.0025.

prop.cens   A value between 0 and 1, 1-prop.cens is the minimum proportion of people who are randomly censored. Represents the quantile to use for generating the random censorship time. In this case, the censorship time follows a uniform distribution in 1 and (prop.cens)ieme percentile of the generated death times. If this argument is set to 0, the fix censorship is considered. The default is 0. Required if type.joint.simul = 3.

time.cens   Censorship time. If argument prop.cens is set to 0, it represents the administrative censorship time, else it represents the fix censoring time. The default is 549, for about 40% of fix censored subjects.

R2   Desired R^2_{trial}. The default is 0.81.

sigma.s   True value for $\sigma^2_{v_S}$ The default is 0.7.

sigma.t   True value for $\sigma^2_{v_T}$. The default is 0.7.

kappa.use   A numeric, that indicates how to manage the smoothing parameters k_1 and k_2 in the event of convergence issues. If it is set to 0, the first smoothing parameters that allowed convergence on the first dataset is used for all simulations. if it is set to 1, a smoothing parameter is estimated by cross-validation for each dataset generated. If it is set to 2, the same process for chosing kappas as in the event 1 is used, but in the event of convergence issue, the first smoothing parameters that allowed convergence among the three previous that have worked is used. If it is

set to 3, the associated smoothing parameters are successively divided by 10, in the event of convergence issues until 5 times. If it is set to 4, the management of the smoothing parameters is as in the event 2, preceded by the successive division described in the event 3 and by the changing of the number of nodes for the Gauss-Hermite quadrature. The default is 4.

random   A binary that says if we reset the random number generation with a different environment at each call (1) or not (0). If it is set to 1, we use the computer clock as seed. In the last case, it is not possible to reproduce the generated datasets. The default is 0. Required if random.generator is set to 1.

random.nb.sim   If random is set to 1, a binary that indicates the number of generations that will be made, equal to nb.dataset in this case.

seed   The seed to use for data generation. Required if random is set to 0. The default is 0.

nb.reject.data   When the simulations have been split into several packets, this argument indicates the number of generated datasets to reject before starting the simulations studies. This prevents to reproduce the same datasets for all simulation packages. It must be set to 0 if just one packet is considered, the default. Otherwise for each packet of simulation run, this value must be updated. e.g. If 10 packets are considered for a total of 100 datasets, one can assigned 0 for the first packet run, 10 for the second, 20 for the 3rd, ... , 90 for the 10th. If this argument is different to 0, the argument nb.dataset must be set to the number of dataset to consider in the packet.

init.kappa   smoothing parameter used to penalized the log-likelihood. By default (init.kappa = NULL) the values used are obtain by cross-validation.

ckappa   Vector of two constantes to add to the smoothing parameters. By default it is set to (0,0). this argument allows to well manage the smoothing parameters in the event of convergence issues.

type.joint.estim

                  Model to considered for the estimation. If this argument is set to 1, the joint surrogate model is used, the default (see jointSurroPenal). If set to 3, parameters are estimated under the joint frailty-copula model for surrogacy (see jointSurroCopPenal).

type.joint.simul

                  Model to considered for data generation. If this argument is set to 1, the joint surrogate model is used, the default (see jointSurroPenal). If set to 3, data are generated following the joint frailty-copula model for surrogacy (see jointSurroCopPenal).

mbetast   Matrix or dataframe containing the true fixed traitment effects associated with the covariates. This matrix includes two columns (first one for surrogate endpoint and second one for true endpoint) and the number of row corresponding to the number of covariate. Require if type.joint.simul = 3 with more than one covariate. The default is NULL and assume only the treatment effect

mbetast.init   Matrix or dataframe containing the initial values for the fixed effects associated with the covariates. This matrix include two columns (first one for surrogate endpoint and second one for true endpoint) and the number of row corresponding to the number of covariate. Require if type.joint.simul = 3 with more than one covariate. The default is NULL and assume only the treatment effect

typecopula	The copula function used for estimation: 1 = clayton, 2 = Gumbel. Require if `type.joint.simul` = 3, the default is 1
theta.copula	The copula parameter. Require if `type.joint.simul` = 3. The default is 6, for an individual-level association (kendall's τ) of 0.75 in the event of Clayton copula
thetacopula.init	
	Initial value for the copula parameter. Require if `type.joint.estim` = 3, the default is 3
filter.surr	Vector of size the number of covariates, with the i-th element that indicates if the hazard for surrogate is adjusted on the i-th covariate (code 1) or not (code 0). By default, only the treatment effect is considered.
filter.true	Vector defines as `filter.surr`, for true endpoint. `filter.true` and `filter.surr` should have the same size
nb.decimal	Number of decimal required for results presentation.
pfs	Is used to specified if the time to progression should be censored by the death time (0) or not (1). The default is 0. In the event with pfs set to 1, death is included in the surrogate endpoint as in the definition of PFS or DFS.
print.times	a logical parameter to print estimation time. Default is TRUE.
print.iter	a logical parameter to print iteration process. Default is FALSE.

Details

The estimated parameter are obtained using the robust Marquardt algorithm (Marquardt, 1963) which is a combination between a Newton-Raphson algorithm and a steepest descent algorithm. The iterations are stopped when the difference between two consecutive log-likelihoods was small ($< 10^{-3}$), the estimated coefficients were stable (consecutive values ($< 10^{-3}$), and the gradient small enough ($< 10^{-3}$), by default. Cubic M-splines of order 4 are used for the hazard function, and I-splines (integrated M-splines) are used for the cumulative hazard function.

The inverse of the Hessian matrix is the variance estimator and to deal with the positivity constraint of the variance component and the spline coefficients, a squared transformation is used and the standard errors are computed by the Δ-method (Knight & Xekalaki, 2000). The smooth parameter can be chosen by maximizing a likelihood cross validation criterion (Joly and other, 1998).

We proposed based on the joint surrogate model a new definition of the Kendall's τ. By cons, for the joint frailty-copula model, we based the individual-level association on a definition of τ clause to that of the classical two-step approch (Burzykowski et al, 2001), but conditional on the random effects. Moreover, distinct numerical integration methods are available to approximate the integrals in the marginal log-likelihood.

Non-convergence case management procedure

Special attention must be given to initializing model parameters, the choice of the number of spline knots, the smoothing parameters and the number of quadrature points to solve convergence issues. We first initialized parameters using the user's desired strategy, as specified by the option `true.init.val`. When numerical or convergence problems are encountered, with `kappa.use` set to 4, the model is fitted again using a combination of the following strategies: vary the number of quadrature point (`nb.gh` to `nb.gh2` or `nb.gh2` to `nb.gh`) in the event of the use of the Gaussian Hermite quadrature integration (see `int.method`); divided or multiplied the smoothing parameters

(k_1 , k_2) by 10 or 100 according to their preceding values, or used parameter vectors obtained during the last iteration (with a modification of the number of quadrature points and smoothing parameters). Using this strategy, we usually obtained during simulation the rejection rate less than 3%. A sensitivity analysis was conducted without this strategy, and similar results were obtained on the converged samples, with about a 23% rejection rate.

Value

This function returns an object of class jointSurroPenalSimul with elements :

theta2	True value for θ, if `type.joint.estim` = 1;
theta.copula	Copula parameter, if `type.joint.estim` = 3;
zeta	true value for ζ, if `type.joint.estim` = 1;
gamma.ui	true value for γ;
alpha.ui	true value for α;
sigma.s	true value for $\sigma_{v_S}^2$;
sigma.t	true value for $\sigma_{v_T}^2$;
sigma.st	true value for $\sigma_{v_{ST}}$;
betas	true value for β_S ;
betat	true value for β_T ;
R2	true value for R_{trial}^2 ;
nb.subject	total number of subjects used;
nb.trials	total number of trials used;
nb.simul	number of simulated datasets;
nb.gh	number of nodes for the Gaussian-Hermite quadrature;
nb.gh2	number of nodes for the Gauss-Hermite quadrature used to re-estimate the model, in the event of non-convergence;
nb.mc	number of samples considered in the Monte-Carlo integration;
kappa.use	a numeric, that indicates how to manage the smoothing parameters k_1 and k_2 in the event of convergence issues;
n.knots	number of knots used for splines;
int.method	integration method used;
n.iter	mean number of iterations needed to converge;
dataTkendall	a matrix with nb.dataset line(s) and three columns, of the estimates of Kendall's τ and theirs confidence intervals (obtained using parametric bootstrap if `type.joint.estim` = 1 or Delta method if `type.joint.estim` = 3). All non-convergence cases are represented by a line of 0;
dataR2boot	a matrix with nb.dataset line(s) and three columns, of the estimates of R_{trial}^2 and theirs confidence intervals using the parametric bootstrap. All non-convergence cases are represented by a line of 0.
dataParamEstim	a dataframe including all estimates with the associated standard errors, for all simulation. All non-convergence cases are represented by a line of 0;

dataHessian	Dataframe of the variance-Covariance matrices of the estimates for all simulations
dataHessianIH	Dataframe of the robust estimation of the variance matrices of the estimates for all simulations
datab	Dataframe of the estimates for all simulations which rich convergence
type.joint	the estimation model; 1 for the joint surrogate and 3 for joint frailty-copula model
type.joint.simul	The model used for data generation; 1 for joint surrogate and 3 for joint frailty-copula
true.init.val	Indicates if the real parameter values have been used as initial values for the model (1), or the given initial values (0)

jointSurroTKendall   *Kendall's τ estimation using numerical integration methods*

Description

This function estimate the Kendall's τ based on the joint surrogate model described in jointSurroPenal (Sofeu *et al.*, 2018), for the evaluation of a candidate surrogate endpoints, at the individual-level . We used the Monte-carlo and the gaussian Hermite quadrature methods for numerical integration. in the event of Gaussian Hermite quadrature, it is better to choose at least 20 quadature nodes for better results. The actual value of nodes used is the maximum between 20 and nb.gh

Usage

```
jointSurroTKendall(object = NULL, theta, gamma, alpha = 1, zeta = 1,
                   sigma.v = matrix(rep(0,4),2,2), int.method = 0,
                   nb.MC.kendall = 10000, nb.gh = 32,
                   random.generator = 1, random = 0,
                   random.nb.sim = 0, seed = 0, ui = 1)
```

Arguments

object   An object inheriting from jointSurroPenal class. The default is NULL

theta   Variance of the individual-level random effect, ω_{ij} . Required if object is set to NULL

gamma   Variance of the trial-level random effect associated with the baseline risk, u_i . Required if object is set to NULL. The default is 3.5.

alpha   Power parameter associated with u_i . Required if object is set to NULL. The default is 1.

zeta   Power parameter associated with ω_{ij} . Required if object is set to NULL The default is 1.

sigma.v	Covariance matrix of the random effects treatment-by-trial interaction (v_{S_i}, v_{T_i})
int.method	A numeric, indicates the integration method: 0 for Monte carlo and 1 for Gaussian-Hermite quadrature. The default is 0
nb.MC.kendall	Number of generated points used with the Monte-Carlo to estimate integrals in the Kendall's τ formulation. Beter to use at least 4000 points for stable results. The default is 10000.
nb.gh	Number of nodes for the Gaussian-Hermite quadrature. The default is 32.
random.generator	
	Random number generator to use by the Fortran compiler, 1 for the intrinsec subroutine Random_number and 2 for the subroutine uniran(). The default is 1.
random	A binary that says if we reset the random number generation with a different environment at each call (1) or not (0). If it is set to 1, we use the computer clock as a seed. In the last case, it is not possible to reproduce the generated datesets". The default is 0.
random.nb.sim	If random is set to 1, a binary that indicates the number of generations that will be made.
seed	The seed to use for data (or samples) generation. required if random is set to 0. The default is 0.
ui	A binary, indicates whether one considered trial random effect associated with the baseline risk (1) or not (0). The default is 1.

Value

This function return the estimated Kendall's τ

    prop.subj.trial = NULL,
    prop.subj.trt = NULL,
    full.data = 0,
    random.generator = 1,
    random = 0,
    random.nb.sim = 0,
    seed = 0,
    nb.reject.data = 0,
    pfs = 0
)
```

Arguments

`n.obs`	Number of considered subjects. The default is `600`.
`n.trial`	Number of considered trials. The default is `30`.
`cens.adm`	censorship time. The default is `549`, for about 40% of censored subjects.
`alpha`	Fixed value for α. The default is `1.5`.
`theta`	Fixed value for θ. The default is `3.5`.
`gamma`	Fixed value for γ. The default is `2.5`.
`zeta`	Fixed value for ζ. The default is `1`.
`sigma.s`	Fixed value for $\sigma^2_{v_S}$. The default is `0.7`.
`sigma.t`	Fixed value for $\sigma^2_{v_T}$. The default is `0.7`.
`cor`	Desired level of correlation between v_{S_i} and v_{T_i}. $R^2_{trial} = cor^2$. The default is `0.8`.
`betas`	Fixed value for β_S. The default is `-1.25`.
`betat`	Fixed value for β_T. The default is `-1.25`.
`frailt.base`	considered the heterogeneity on the baseline risk (`1`) or not (`0`). The default is `1`.
`lambda.S`	Desired scale parameter for the `Weibull` distribution associated with the Surrogate endpoint. The default is 1.8.
`nu.S`	Desired shape parameter for the `Weibull` distribution associated with the Surrogate endpoint. The default is 0.0045.
`lambda.T`	Desired scale parameter for the `Weibull` distribution associated with the True endpoint. The default is 3.
`nu.T`	Desired shape parameter for the `Weibull` distribution associated with the True endpoint. The default is 0.0025.
`ver`	Number of covariates. For surrogte evaluation, we just considered one covatiate, the treatment arm
`typeOf`	Type of joint model used for data generation: 0 = classical joint model with a shared individual frailty effect (Rondeau, 2007), 1 = joint surrogate model with shared frailty effects u_i and ω_{ij}, and two correlated random effects treatment-by-trial interaction (v_{S_i}, v_{T_i}) as described in Sofeu et al. (2018).

equi.subj.trial

    A binary variable that indicates if the same proportion of subjects should be included per trial (1) or not (0). If 0, the proportions of subject per trial are required in parameter `prop.subj.trial`.

equi.subj.trt   A binary variable that indicates if the same proportion of subjects is randomized per trial (1) or not (0). If 0, the proportions of subject per trial are required in parameter `prop.subj.trt`.

prop.subj.trial

    The proportions of subjects per trial. Requires if `equi.subj.trial=0`.

prop.subj.trt   The proportions of randomized subject per trial. Requires if `equi.subj.trt=0`.

full.data   Specified if you want the function to return the full dataset (1), including the random effects, or the restictive dataset (0) with 7 columns required for the function jointSurroPenal.

random.generator

    Random number generator used by the Fortran compiler, 1 for the intrinsec subroutine Random_number and 2 for the subroutine uniran(). The default is 1.

random   A binary that says if we reset the random number generation with a different environment at each call (1) or not (0). If it is set to 1, we use the computer clock as seed. In the last case, it is not possible to reproduce the generated datasets. The default is 0. Required if `random.generator` is set to 1.

random.nb.sim   required if `random.generator` is set to 1, and if `random` is set to 1.

seed   The seed to use for data (or samples) generation. Required if the argument `random.generator` is set to 1. Must be a positive value. If negative, the program do not account for seed. The default is 0.

nb.reject.data   Number of generation to reject before the considered dataset. This parameter is required when data generation is for simulation. With a fixed parameter and `random.generator` set to 1, all ganerated data are the same. By varying this parameter, different datasets are obtained during data genarations. The default value is 0, in the event of one dataset.

pfs   Is used to specify if the time to progression should be censored by the death time (0) or not (1). The default is 0. In the event with pfs set to 1, death is included in the surrogate endpoint as in the definition of PFS or DFS.

Details

We just considered in this generation, the Gaussian random effects. If the parameter `full.data` is set to 1, this function return a list containning severals parameters, including the generated random effects. the desired individual level correlation (Kendall's τ) depend on the values of α, θ, γ and ζ.

Value

This function return if the parameter `full.data` is set to 0, a data.frame with columns :

patientID   A numeric, that represents the patient's identifier, must be unique;

trialID   A numeric, that represents the trial in which each patient was randomized;

trt   The treatment indicator for each patient, with 1 = treated, 0 = untreated;

timeS	The follow up time associated with the surrogate endpoint;
statusS	The event indicator associated with the surrogate endpoint. Normally 0 = no event, 1 = event;
timeT	The follow up time associated with the true endpoint;
statusT	The event indicator associated with the true endpoint. Normally 0 = no event, 1 = event;

If the argument `full.data` is set to 1, additionnal colums corresponding to random effects ω_{ij} , u_i , v_{S_i} and v_{T_i} are returned. Note that u_i , v_{S_i} and v_{T_i} are returned if `typeOf` is set to 1

longDat   *Longitudinal semicontinuous biomarker dataset (TPJM)*

Description

This is a simulated dataset used to illustrate the two-part joint model included in the longiPenal function.

Usage

```
data(longDat)
```

Format

This data frame contains the following columns:

id The identification number of a patient

timej The measurement times of the biomarker

trtY Treatment covariate

Y Biomarker value

---

longiPenal   *Fit a Joint Model for Longitudinal Data and a Terminal Event*

Description

Fit a joint model for longitudinal data and a terminal event using a semiparametric penalized likelihood estimation or a parametric estimation on the hazard function.

The longitudinal outcomes $y_i(t_{ik})$ ($k = 1, \ldots, n_i$, $i = 1, \ldots, N$) for N subjects are described by a linear mixed model and the risk of the terminal event is represented by a proportional hazard risk model. The joint model is constructed assuming that the processes are linked via a latent structure (Wulfsohn and Tsiatsis 1997):

$$\begin{cases} y_i(t_{ik}) = \boldsymbol{X}_{Li}(t_{ik})^\top \boldsymbol{\beta}_L + \boldsymbol{Z}_i(t_{ik})^\top \boldsymbol{b}_i + \epsilon_i(t_{ik}) & \text{(Longitudinal)} \\ \lambda_i(t|\boldsymbol{b}_i) = \lambda_0(t) \exp(\boldsymbol{X}_{Ti}(t)\boldsymbol{\beta}_T + h(\boldsymbol{b}_i, \boldsymbol{\beta}_L, \boldsymbol{Z}_i(t), \boldsymbol{X}_{Li}(t))^\top \boldsymbol{\eta}_T) & \text{(Terminal)} \end{cases}$$

where $\boldsymbol{X}_{Li}(t)$ and $\boldsymbol{X}_{Ti}$ are vectors of fixed effects covariates and $\boldsymbol{\beta}_L$ and $\boldsymbol{\beta}_T$ are the associated coefficients. Measurements errors $\epsilon_i(t_{ik})$ are iid normally distributed with mean 0 and variance σ_ϵ^2. The random effects $\boldsymbol{b}_i = (b_{0i}, \ldots, b_{qi})^\top \sim \mathcal{N}(0, \boldsymbol{B}_1)$ are associated to covariates $\boldsymbol{Z}_i(t)$ and independent from the measurement error. The relationship between the two processes is explained via $h(\boldsymbol{b}_i, \boldsymbol{\beta}_L, \boldsymbol{Z}_i(t), \boldsymbol{X}_{Li}(t))$ with coefficients $\boldsymbol{\eta}_T$. Two forms of the function $h(\cdot)$ are available: the random effects $\boldsymbol{b}_i$ and the current biomarker level $m_i(t) = \boldsymbol{X}_{Li}(t_{ik})^\top \boldsymbol{\beta}_L + \boldsymbol{Z}_i(t_{ik})^\top \boldsymbol{b}_i$.

We consider that the longitudinal outcome can be a subject to a quantification limit, i.e. some observations, below a level of detection s cannot be quantified (left-censoring).

Usage

```
longiPenal(formula, formula.LongitudinalData, data, data.Longi,
  formula.Binary=FALSE, random, random.Binary=FALSE, fixed.Binary=FALSE,
  GLMlog=FALSE, MTP=FALSE, id, intercept = TRUE,
  link = "Random-effects", timevar=FALSE, left.censoring =
  FALSE, n.knots, kappa, maxit = 350, hazard = "Splines", init.B,
 init.Random, init.Eta, method.GH = "Standard", seed.MC=1, n.nodes, LIMparam = 1e-3,
  LIMlogl = 1e-3, LIMderiv = 1e-3, print.times = TRUE)
```

Arguments

formula   a formula object, with the response on the left of a $\sim$ operator, and the terms
                 on the right. The response must be a survival object as returned by the 'Surv'
                 function like in survival package. Interactions are possible using * or :.

formula.LongitudinalData

                 a formula object, only requires terms on the right to indicate which variables are
                 modelling the longitudinal outcome. It must follow the standard form used for
                 linear mixed-effects models. Interactions are possible using * or :.

data   a 'data.frame' with the variables used in formula.

data.Longi   a 'data.frame' with the variables used in formula.LongitudinalData.

formula.Binary   a formula object, only requires terms on the right to indicate which variables are
                 modelling the binary part of the two-part model fitting the longitudinal semicon-
                 tinuous outcome. It must follow the standard form used for linear mixed-effects
                 models. Interactions are possible using * or :.

random   Names of variables for the random effects of the longitudinal outcome. Max-
                 imum 3 random effects are possible at the moment. The random intercept is
                 chosen using "1".

random.Binary   Names of variables for the random effects of the binary part of the two-part
                 model fitting the longitudinal semicontinuous outcome. The random intercept is
                 chosen using "1".

fixed.Binary   Fix the value of the intercept in the binary part of a two-part model.

GLMlog   Logical value. Use a lognormal distribution for the biomarker (instead of the
                 default normal distribution).

MTP   Logical value. Marginal two-part joint model instead of conditional two-part
                 joint model (only with two-part models).

id   Name of the variable representing the individuals.

intercept   Logical value. Is the fixed intercept of the biomarker included in the mixed-
                 effects model? The default is TRUE.

link   Type of link function for the dependence between the biomarker and death:
                 "Random-effects" for the association directly via the random effects of the
                 biomarker, "Current-level" for the association via the true current level of the
                 biomarker. The option "Current-level" can be chosen only if the biomarker
                 random effects are associated with the intercept and time (following this order).
                 "Two-part", this structure is only applicable with conditional two-part models,

the effect of the current probability of positive value and the effect of the expected value among positive values on the risk of event is evaluated separately. The default is "Random-effects".

timevar   Indicates the time varying variables to take into account this evolution over time in the link with the survival model (useful with 'Current-level' and 'Two-part' links)

left.censoring   Is the biomarker left-censored below a threshold s? The default is FALSE, ie. no left-censoring. In case of a left-censored biomarker, this argument must be equal to the threshold s.

n.knots   Integer giving the number of knots to use. Value required in the penalized likelihood estimation. It corresponds to the (n.knots+2) splines functions for the approximation of the hazard or the survival functions. We estimate I or M-splines of order 4. When the user set a number of knots equals to k (n.knots=k) then the number of interior knots is (k-2) and the number of splines is (k-2)+order. Number of knots must be between 4 and 20. (See Note in frailtyPenal function)

kappa   Positive smoothing parameter in the penalized likelihood estimation. The coefficient kappa of the integral of the squared second derivative of hazard function in the fit (penalized log likelihood). To obtain an initial value for kappa, a solution is to fit the corresponding Cox model using cross validation (See cross.validation in function frailtyPenal). We advise the user to identify several possible tuning parameters, note their defaults and look at the sensitivity of the results to varying them.

maxit   Maximum number of iterations for the Marquardt algorithm. The default is 350.

hazard   Type of hazard functions: "Splines" for semiparametric hazard functions using equidistant intervals or "Splines-per" using percentile with the penalized likelihood estimation, "Weibull" for the parametric Weibull functions. The default is "Splines".

init.B   Vector of initial values for regression coefficients. This vector should be of the same size as the whole vector of covariates with the first elements for the covariates related to the terminal event and then for the covariates related to the biomarker (interactions in the end of each component). Default is 0.5 for each.

init.Random   Initial value for variance of the elements of the matrix of the distribution of the random effects. Default is 0.5 for each element.

init.Eta   Initial values for regression coefficients for the link function. Default is 0.5 for each.

method.GH   Method for the Gauss-Hermite quadrature: "Standard" for the standard non-adaptive Gaussian quadrature, "Pseudo-adaptive" for the pseudo-adaptive Gaussian quadrature, "Monte-carlo" for the Monte-carlo method and "HRMSYM" for the algorithm for the multivariate non-adaptive Gaussian quadrature (see Details). The default is "Standard".

seed.MC   Monte-carlo integration points selection (1=fixed, 0=random)

n.nodes   Number of nodes for the Gauss-Hermite quadrature or the Monte-carlo method. They can be chosen among 5, 7, 9, 12, 15, 20 and 32 for the GH quadrature and any number for the Monte-carlo method. The default is 9.

LIMparam	Convergence threshold of the Marquardt algorithm for the parameters (see Details of `frailtyPenal` function), 10^{-3} by default.
LIMlogl	Convergence threshold of the Marquardt algorithm for the log-likelihood (see Details of `frailtyPenal` function), 10^{-3} by default.
LIMderiv	Convergence threshold of the Marquardt algorithm for the gradient (see Details of `frailtyPenal` function), 10^{-3} by default.
print.times	a logical parameter to print iteration process. The default is TRUE.

Details

Typical usage for the joint model

```
longiPenal(Surv(time,event)~var1+var2, biomarker ~ var1+var2,
data, data.Longi, ...)
```

The method of the Gauss-Hermite quadrature for approximations of the multidimensional integrals, i.e. length of `random` is 2, can be chosen among the standard, non-adaptive, pseudo-adaptive in which the quadrature points are transformed using the information from the fitted mixed-effects model for the biomarker (Rizopoulos 2012) or multivariate non-adaptive procedure proposed by Genz et al. 1996 and implemented in FORTRAN subroutine HRMSYM. The choice of the method is important for estimations. The standard non-adaptive Gauss-Hermite quadrature ("Standard") with a specific number of points gives accurate results but can be time consuming. The non-adaptive procedure ("HRMSYM") offers advantageous computational time but in case of datasets in which some individuals have few repeated observations (biomarker measures or recurrent events), this method may be moderately unstable. The pseudo-adaptive quadrature uses transformed quadrature points to center and scale the integrand by utilizing estimates of the random effects from an appropriate linear mixed-effects model. This method enables using less quadrature points while preserving the estimation accuracy and thus lead to a better computational time.The Monte-Carlo method is also proposed for approximations of the multidimensional integrals.

NOTE. Data frames `data` and `data.Longi` must be consistent. Names and types of corresponding covariates must be the same, as well as the number and identification of individuals.

Value

The following components are included in a 'longiPenal' object for each model:

b	The sequence of the corresponding estimation of the coefficients for the hazard functions (parametric or semiparametric), the random effects variances and the regression coefficients.
call	The code used for the model.
formula	The formula part of the code used for the terminal event part of the model.
formula.LongitudinalData	
	The formula part of the code used for the longitudinal part of the model.
formula.Binary	The formula part of the code used for the binary part of the two-part model.
coef	The regression coefficients (first for the terminal event and then for the biomarker.
groups	The number of groups used in the fit.

kappa	The value of the smoothing parameter in the penalized likelihood estimation corresponding to the baseline hazard function for the terminal event.
logLikPenal	The complete marginal penalized log-likelihood in the semiparametric case.
logLik	The marginal log-likelihood in the parametric case.
n.measurements	The number of biomarker observations used in the fit.
max_rep	The maximal number of repeated measurements per individual.
n.deaths	The number of events observed in the fit.
n.iter	The number of iterations needed to converge.
n.knots	The number of knots for estimating the baseline hazard function in the penalized likelihood estimation.
n.strat	The number of stratum.
varH	The variance matrix of all parameters (before positivity constraint transformation for the variance of the measurement error, for which the delta method is used).
varHIH	The robust estimation of the variance matrix of all parameters.
xD	The vector of times where both survival and hazard function of the terminal event are estimated. By default seq(0,max(time),length=99), where time is the vector of survival times.
lamD	The array (dim=3) of baseline hazard estimates and confidence bands (terminal event).
survD	The array (dim=3) of baseline survival estimates and confidence bands (terminal event).
median	The value of the median survival and its confidence bands.
typeof	The type of the baseline hazard functions (0:"Splines", "2:Weibull").
npar	The number of parameters.
nvar	The vector of number of explanatory variables for the terminal event and biomarker.
nvarEnd	The number of explanatory variables for the terminal event.
nvarY	The number of explanatory variables for the biomarker.
noVarEnd	The indicator of absence of the explanatory variables for the terminal event.
noVarY	The indicator of absence of the explanatory variables for the biomarker.
LCV	The approximated likelihood cross-validation criterion in the semiparametric case (with H minus the converged Hessian matrix, and l(.) the full log-likelihood).

$$LCV = \frac{1}{n}(trace(H_{pl}^{-1}H) - l(.))$$

AIC	The Akaike information Criterion for the parametric case.

$$AIC = \frac{1}{n}(np - l(.))$$

n.knots.temp	The initial value for the number of knots.
shape.weib	The shape parameter for the Weibull hazard function.

scale.weib   The scale parameter for the Weibull hazard function.

martingaledeath.res

          The martingale residuals for each individual.

conditional.res

          The conditional residuals for the biomarker (subject-specific): $\boldsymbol{R}_i^{(m)} = \boldsymbol{y}_i - \boldsymbol{X}_{Li}^{\top}\widehat{\boldsymbol{\beta}}_L - \boldsymbol{Z}_i^{\top}\widehat{\boldsymbol{b}}_i$.

marginal.res   The marginal residuals for the biomarker (population averaged): $\boldsymbol{R}_i^{(c)} = \boldsymbol{y}_i - \boldsymbol{X}_{Li}^{\top}\widehat{\boldsymbol{\beta}}_L$.

marginal_chol.res

          The Cholesky marginal residuals for the biomarker: $\boldsymbol{R}_i^{(m)} = \widehat{\boldsymbol{U}_i^{(m)}}\boldsymbol{R}_i^{(m)}$, where $\widehat{\boldsymbol{U}_i^{(m)}}$ is an upper-triangular matrix obtained by the Cholesky decomposition of the variance matrix $\boldsymbol{V}_{\boldsymbol{R}_i^{(m)}} = \widehat{\boldsymbol{V}}_i - \boldsymbol{X}_{Li}(\sum_{i=1}^{N}\boldsymbol{X}_{Li}\widehat{\boldsymbol{V}}_i^{-1}\boldsymbol{X}_{Li})^{-1}\boldsymbol{X}_{Li}^{\top}$.

conditional_st.res

          The standardized conditional residuals for the biomarker.

marginal_st.res

          The standardized marginal residuals for the biomarker.

random.effects.pred

          The empirical Bayes predictions of the random effects (ie. using conditional posterior distributions).

pred.y.marg   The marginal predictions of the longitudinal outcome.

pred.y.cond   The conditional (given the random effects) predictions of the longitudinal outcome.

lineardeath.pred

          The linear predictor for the terminal part.

global_chisq_d The vector with values of each multivariate Wald test for the terminal part.

dof_chisq_d   The vector with degrees of freedom for each multivariate Wald test for the terminal part.

global_chisq.test_d

          The binary variable equals to 0 when no multivariate Wald is given, 1 otherwise (for the terminal part).

p.global_chisq_d

          The vector with the p_values for each global multivariate Wald test for the terminal part.

global_chisq   The vector with values of each multivariate Wald test for the longitudinal part.

dof_chisq   The vector with degrees of freedom for each multivariate Wald test for the longitudinal part.

global_chisq.test

          The binary variable equals to 0 when no multivariate Wald is given, 1 otherwise (for the longitudinal part).

p.global_chisq The vector with the p_values for each global multivariate Wald test for the longitudinal part.

names.factordc The names of the "as.factor" variables for the terminal part.

names.factor	The names of the "as.factor" variables for the longitudinal part.
intercept	The logical value. Is the fixed intercept included in the linear mixed-effects model?
B1	The variance matrix of the random effects for the longitudinal outcome.
ResidualSE	The standard deviation of the measurement error.
eta	The regression coefficients for the link function.
ne_re	The number of random effects used in the fit.
names.re	The names of variables for the random effects.
link	The name of the type of the link function.
eta_p.value	p-values of the Wald test for the estimated regression coefficients for the link function.
beta_p.value	p-values of the Wald test for the estimated regression coefficients.
leftCensoring	The logical value. Is the longitudinal outcome left-censored?
leftCensoring.threshold	
	For the left-censored biomarker, the value of the left-censoring threshold used for the fit.
prop.censored	The fraction of observations subjected to the left-censoring.
methodGH	The method used for approximations of the multidimensional integrals.
n.nodes	The number of integration points.

```

loocv	*The trials leave-one-out crossvalidation for the one-step Joint surrogate model for evaluating a canditate surrogate endpoint.*

Description

The trials leave-one-out crossvalidation for evaluating the joint surrogate model

Usage

```
loocv(object, unusedtrial, var.used = "error.estim", alpha. = 0.05,
dec = 3, print.times = TRUE)
```

Arguments

object	An object inheriting from jointSurroPenal class (output from calling the function jointSurroPenal or jointSurroCopPenal).
unusedtrial	A list of trial not to be taken into account in the cross-validation. This parameter is useful when after excluding some trials, the model is facing convergence problem.
var.used	This argument takes two values. The first one is "error.estim" and indicates if the prediction variance takes into account the estimation errors from the estimates of the parameters. If estimates are supposed to be known or if the dataset includes a high number of trials with a high number of subject per trial, value "No.error" can be used. The default is error.estim.
alpha.	The confidence level for the prediction interval. The default is 0.05
dec	The desired number of digits after the decimal point for parameters and confidence intervals. Default of 3 digits is used.
print.times	a logical parameter to print estimation time. Default is TRUE.

Value

This function returns an object of class jointSurroPenalloocv containing:

result	A dataframe including for each trial the number of included subjects, the observed treatment effect on the surrogate endpoint, the observed treatment effect on the true endpoint and the predicted treatment effect on the true enpoint with the associated prediction intervals. If the observed treatment effect on the true endpoint is included into the prediction interval, the last columns contains "*".
ntrial	The number of trials in the meta-analysis
notconvtrial	The vector of trials that have not converged
pred.error	The prediction error, corresponding to the number of cases where the prediction interval does not included the observed treatment effect on T
different.models	
	The list of the G models obtained after excuded for the i-th trial
loocv.summary	A dataframe of the estimates for the G models; each raw including the results without the subjects of the given trial

multivPenal   *Fit a multivariate frailty model for two types of recurrent events and a*
                               terminal event.

Description

Fit a multivariate frailty model for two types of recurrent events with a terminal event using a
penalized likelihood estimation on the hazard function or a parametric estimation. Right-censored
data are allowed. Left-truncated data and stratified analysis are not possible. Multivariate frailty
models allow studying, with a joint model, three survival dependent processes for two types of
recurrent events and a terminal event. Multivariate joint frailty models are applicable in mainly two
settings. First, when focus is on the terminal event and we wish to account for the effect of previous
endogenous recurrent event. Second, when focus is on a recurrent event and we wish to correct for
informative censoring.

The multivariate frailty model for two types of recurrent events with a terminal event is (in the
calendar or time-to-event timescale):

$$\begin{cases} r_i^{(1)}(t|u_i, v_i) & = r_0^{(1)}(t)\exp(\beta_1' Z_i(t) + u_i) & \text{(rec. of type 1)} \\ r_i^{(2)}(t|u_i, v_i) & = r_0^{(2)}(t)\exp(\beta_2' Z_i(t) + v_i) & \text{(rec. of type 2)} \\ \lambda_i(t|u_i, v_i) & = \lambda_0(t)\exp(\beta_3' Z_i(t) + \alpha_1 u_i + \alpha_2 v_i) & \text{(death)} \end{cases}$$

where $r_0^{(l)}(t)$, $l \in 1, 2$ and $\lambda_0(t)$ are respectively the recurrent and terminal event baseline hazard functions, and $\beta_1, \beta_2, \beta_3$ the regression coefficient vectors associated with $Z_i(t)$ the covariate vector. The covariates could be different for the different event hazard functions and may be time-dependent. We consider that death stops new occurrences of recurrent events of any type, hence given $t > D$, $dN^{R(l)*}(t), l \in 1, 2$ takes the value 0. Thus, the terminal and the two recurrent event processes are not independent or even conditional upon frailties and covariates. We consider the hazard functions of recurrent events among individuals still alive. components in the above multivariate frailty model are linked together by two Gaussian and correlated random effects u_i, v_i: $(u_i, v_i)^T \sim \mathcal{N}(0, \Sigma_{uv})$, with

$$\Sigma_{uv} = \begin{pmatrix} \theta_1 & \rho\sqrt{\theta_1\theta_2} \\ \rho\sqrt{\theta_1\theta_2} & \theta_2 \end{pmatrix}$$

Dependencies between these three types of event are taken into account by two correlated random effects and parameters θ_1, θ_2 the variance of the random effects and α_1, α_2 the coefficients for these random effects into the terminal event part. If α_1 and θ_1 are both significantly different from 0, then the recurrent events of type 1 and death are significantly associated (the sign of the association is the sign of α_1). If α_2 and θ_2 are both significantly different from 0, then the recurrent events of type 2 and death are significantly associated (the sign of the association is the sign of α_2). If ρ, the correlation between the two random effects, is significantly different from 0, then the recurrent events of type 1 and the recurrent events of type 2 are significantly associated (the sign of the association is the sign of ρ).

Usage

```
multivPenal(formula, formula.Event2, formula.terminalEvent, data, initialize
= TRUE, recurrentAG = FALSE, n.knots, kappa, maxit = 350, hazard =
"Splines", nb.int, print.times = TRUE)
```

Arguments

formula   a formula object, with the response for the first recurrent event on the left of a $\sim$ operator, and the terms on the right. The response must be a survival object as returned by the 'Surv' function like in survival package. Interactions are possible using * or :.

formula.Event2   a formula object, with the response for the second recurrent event on the left of a $\sim$ operator, and the terms on the right. The response must be a survival object as returned by the 'Surv' function like in survival package. Interactions are possible using * or :.

formula.terminalEvent
                 a formula object, with the response for the terminal event on the left of a $\sim$ operator, and the terms on the right. The response must be a survival object as returned by the 'Surv' function like in survival package.

data   a 'data.frame' with the variables used in 'formula', 'formula.Event2' and 'for-mula.terminalEvent'.

initialize   Logical value to initialize regression coefficients and baseline hazard functions parameters. When the estimation is semi-parametric with splines, this initialization produces also values for smoothing parameters (by cross validation). When initialization is requested, the program first fit two shared frailty models (for the two types of recurrent events) and a Cox proportional hazards model (for the terminal event). Default is TRUE.

recurrentAG   Logical value. Is Andersen-Gill model fitted? If so indicates that recurrent event times with the counting process approach of Andersen and Gill is used. This formulation can be used for dealing with time-dependent covariates. The default is FALSE.

n.knots   integer vector of length 3 (for the three outcomes) giving the number of knots to use. First is for the recurrent of type 1, second is for the recurrent of type 2 and third is for the terminal event hazard function. Value required in the penalized likelihood estimation. It corresponds to the (n.knots+2) splines functions for the approximation of the hazard or the survival functions. Number of knots must be between 4 and 20. (See Note)

kappa   vector of length 3 (for the three outcomes) for positive smoothing parameters in the penalized likelihood estimation. First is for the recurrent of type 1, second is for the recurrent of type 2 and third is for the terminal event hazard function. The coefficient kappa of the integral of the squared second derivative of hazard function in the fit (penalized log likelihood). Initial values for the kappas can be obtained with the option "initialize=TRUE". We advise the user to identify several possible tuning parameters, note their defaults and look at the sensitivity of the results to varying them. Value required.(See Note)

maxit   maximum number of iterations for the Marquardt algorithm. Default is 350.

hazard   Type of hazard functions: "Splines" for semi-parametric hazard functions with the penalized likelihood estimation, "Piecewise-per" for piecewise constant haz-ard function using percentile, "Piecewise-equi" for piecewise constant hazard function using equidistant intervals, "Weibull" for parametric Weibull function. Default is "Splines".

nb.int   An integer vector of length 3 (for the three outcomes). First is the Number of intervals (between 1 and 20) for the recurrent of type 1 parametric hazard functions ("Piecewise-per", "Piecewise-equi"). Second is the Number of inter-vals (between 1 and 20) for the recurrent of type 2 parametric hazard functions ("Piecewise-per", "Piecewise-equi"). Third is Number of intervals (between 1 and 20) for the death parametric hazard functions ("Piecewise-per", "Piecewise-equi")

print.times   a logical parameter to print iteration process. Default is TRUE.

Value

Parameters estimates of a multivariate joint frailty model, more generally a 'multivPenal' object. Methods defined for 'multivPenal' objects are provided for print, plot and summary. The following components are included in a 'multivPenal' object for multivariate Joint frailty models.

b	sequence of the corresponding estimation of the splines coefficients, the random effects variances, the coefficients of the frailties and the regression coefficients.
call	The code used for fitting the model.
n	the number of observations used in the fit.
groups	the number of subjects used in the fit.
n.events	the number of recurrent events of type 1 observed in the fit.
n.events2	the number of the recurrent events of type 2 observed in the fit.
n.deaths	the number of deaths observed in the fit.
loglikPenal	the complete marginal penalized log-likelihood in the semi-parametric case.
loglik	the marginal log-likelihood in the parametric case.
LCV	the approximated likelihood cross-validation criterion in the semi parametric case (with H minus the converged Hessian matrix, and l(.) the full log-likelihood.

$$LCV = \frac{1}{n}(trace(H_{pl}^{-1}H) - l(.))$$

)

AIC	the Akaike information Criterion for the parametric case.

$$AIC = \frac{1}{n}(np - l(.))$$

theta1	variance of the frailty parameter for recurrences of type 1 ($\boldsymbol{Var}(u_i)$)
theta2	variance of the frailty parameter for recurrences of type 2 ($\boldsymbol{Var}(v_i)$)
alpha1	the coefficient associated with the frailty parameter u_i in the terminal hazard function.
alpha2	the coefficient associated with the frailty parameter v_i in the terminal hazard function.
rho	the correlation coefficient between u_i and v_i
npar	number of parameters.
coef	the regression coefficients.
nvar	A vector with the number of covariates of each type of hazard function as components.
varH	the variance matrix of all parameters before positivity constraint transformation (theta, the regression coefficients and the spline coefficients). Then, the delta method is needed to obtain the estimated variance parameters.
varHIH	the robust estimation of the variance matrix of all parameters (theta, the regression coefficients and the spline coefficients).
formula	the formula part of the code used for the model for the recurrent event.
formula.Event2	the formula part of the code used for the model for the second recurrent event.
formula.terminalEvent	
	the formula part of the code used for the model for the terminal event.

x1	vector of times for hazard functions of the recurrent events of type 1 are estimated. By default seq(0,max(time),length=99), where time is the vector of survival times.
lam1	matrix of hazard estimates and confidence bands for recurrent events of type 1.
xSu1	vector of times for the survival function of the recurrent event of type 1.
surv1	matrix of baseline survival estimates and confidence bands for recurrent events of type 1.
x2	vector of times for the recurrent event of type 2 (see x1 value).
lam2	the same value as lam1 for the recurrent event of type 2.
xSu2	vector of times for the survival function of the recurrent event of type 2
surv2	the same value as surv1 for the recurrent event of type 2.
xEnd	vector of times for the terminal event (see x1 value).
lamEnd	the same value as lam1 for the terminal event.
xSuEnd	vector of times for the survival function of the terminal event
survEnd	the same value as surv1 for the terminal event.
median1	The value of the median survival and its confidence bands for the recurrent event of type 1.
median2	The value of the median survival and its confidence bands for the recurrent event of type 2.
medianEnd	The value of the median survival and its confidence bands for the terminal event.
type.of.Piecewise	
	Type of Piecewise hazard functions (1:"percentile", 0:"equidistant").
n.iter	number of iterations needed to converge.
type.of.hazard	Type of hazard functions (0:"Splines", "1:Piecewise", "2:Weibull").
n.knots	a vector with number of knots for estimating the baseline functions.
kappa	a vector with the smoothing parameters in the penalized likelihood estimation corresponding to each baseline function as components.
n.knots.temp	initial value for the number of knots.
zi	splines knots.
time	knots for Piecewise hazard function for the recurrent event of type 1.
timedc	knots for Piecewise hazard function for the terminal event.
time2	knots for Piecewise hazard function for the recurrent event of type 2.
noVar	indicator vector for recurrent, death and recurrent 2 explanatory variables.
nvarRec	number of the recurrent of type 1 explanatory variables.
nvarEnd	number of death explanatory variables.
nvarRec2	number of the recurrent of type 2 explanatory variables.
nbintervR	Number of intervals (between 1 and 20) for the the recurrent of type 1 parametric hazard functions ("Piecewise-per", "Piecewise-equi").
nbintervDC	Number of intervals (between 1 and 20) for the death parametric hazard functions ("Piecewise-per", "Piecewise-equi").

nbintervR2	Number of intervals (between 1 and 20) for the the recurrent of type 2 parametric hazard functions ("Piecewise-per", "Piecewise-equi").
istop	Vector of the convergence criteria.
shape.weib	shape parameters for the Weibull hazard function.
scale.weib	scale parameters for the Weibull hazard function.
martingale.res	martingale residuals for each cluster (recurrent of type 1).
martingale2.res	
	martingale residuals for each cluster (recurrent of type 2).
martingaledeath.res	
	martingale residuals for each cluster (death).
frailty.pred	empirical Bayes prediction of the first frailty term.
frailty2.pred	empirical Bayes prediction of the second frailty term.
frailty.var	variance of the empirical Bayes prediction of the first frailty term.
frailty2.var	variance of the empirical Bayes prediction of the second frailty term.
frailty.corr	Correlation between the empirical Bayes prediction of the two frailty.
linear.pred	linear predictor: uses Beta'X + ui in the multivariate frailty models.
linear2.pred	linear predictor: uses Beta'X + vi in the multivariate frailty models.
lineardeath.pred	
	linear predictor for the terminal part form the multivariate frailty models: Beta'X + alpha1 ui + alpha2 vi
global_chisq	Recurrent event of type 1: a vector with the values of each multivariate Wald test.
dof_chisq	Recurrent event of type 1: a vector with the degree of freedom for each multivariate Wald test.
global_chisq.test	
	Recurrent event of type 1: a binary variable equals to 0 when no multivariate Wald is given, 1 otherwise.
p.global_chisq	Recurrent event of type 1: a vector with the p-values for each global multivariate Wald test.
names.factor	Recurrent event of type 1: Names of the "as.factor" variables.
global_chisq2	Recurrent event of type 2: a vector with the values of each multivariate Wald test.
dof_chisq2	Recurrent event of type 2: a vector with the degree of freedom for each multivariate Wald test.
global_chisq.test2	
	Recurrent event of type 2: a binary variable equals to 0 when no multivariate Wald is given, 1 otherwise.
p.global_chisq2	
	Recurrent event of type 2: a vector with the p_values for each global multivariate Wald test.
names.factor2	Recurrent event of type 2: Names of the "as.factor" variables.
global_chisq_d	Terminal event: a vector with the values of each multivariate Wald test.

dof_chisq_d   Terminal event: a vector with the degree of freedom for each multivariate Wald
                    test.
global_chisq.test_d
                    Terminal event: a binary variable equals to 0 when no multivariate Wald is given,
                    1 otherwise.
p.global_chisq_d
                    Terminal event: a vector with the p-values for each global multivariate Wald
                    test.
names.factordc   Terminal event: Names of the "as.factor" variables.

Note

"kappa" (kappa[1], kappa[2] and kappa[3]) and "n.knots" (n.knots[1], n.knots[2] and n.knots[3])
are the arguments that the user has to change if the fitted model does not converge. "n.knots" takes
integer values between 4 and 20. But with n.knots=20, the model will take a long time to converge.
So, usually, begin first with n.knots=7, and increase it step by step until it converges. "kappa" only
takes positive values. So, choose a value for kappa (for instance 10000), and if it does not converge,
multiply or divide this value by 10 or 5 until it converges. Moreover, it may be useful to change the
value of the initialize argument.

num.id   *Identify individuals in Joint model for clustered data*

Description

This is a special function used in addition to the cluster() function in the context of survival joint models for clustered data. This function identifies subject index. It is used on the right hand side of a 'frailtyPenal' formula. Using num.id() in a formula implies that a joint frailty model for clustered data is fitted (Rondeau et al. 2011).

Usage

```
num.id(x)
```

Arguments

x   A character or numeric variable which is supposed to indicate the variable iden-
                tifying individuals

References

V. Rondeau, J.P. Pignon, S. Michiels (2011). A joint model for the dependence between clustered times to tumour progression and deaths: A meta-analysis of chemotherapy in head and neck cancer. *Statistical methods in medical research* **897**, 1-19.

plot.additivePenal   *Plot Method for an Additive frailty model.*

Description

Plots estimated baseline survival and hazard functions (output from an object of class'additivePenal'
object for additive frailty model). Confidence bands are allowed.

Usage

```
## S3 method for class 'additivePenal'
plot(x, type.plot="Hazard", conf.bands=TRUE,
pos.legend="topright", cex.legend=0.7, main, color=2, median=TRUE, Xlab = "Time", Ylab =
"Hazard function", ...)
```

Arguments

x	An object of a fitted additive frailty model (output from calling additivePenal).
type.plot	a character string specifying the type of curve. Possible value are "Hazard", or "Survival". The default is "Hazard". Only the first words are required, e.g "Haz", "Su"
conf.bands	logical value. Determines whether confidence bands will be plotted. The default is to do so.

pos.legend	The location of the legend can be specified by setting this argument to a single keyword from the list '"bottomright"', '"bottom"', '"bottomleft"', '"left"', '"topleft"', '"top"', '"topright"', '"right"' and '"center"'. The default is '"topright"'
cex.legend	character expansion factor *relative* to current 'par("cex")'. Default is 0.7
main	plot title
color	curve color (integer)
median	Logical value. Determines whether survival median will be plotted. Default is TRUE.
Xlab	Label of x-axis. Default is '"Time"'
Ylab	Label of y-axis. Default is '"Hazard function"'
...	Other graphical parameters like those in [plot.frailtyPenal](#)

Value

Print a plot of the baseline survival or hazard functions with the confidence bands or not (conf.bands argument)

See Also

---

plot.Diffepoce   *Plot difference of EPOCE estimators between two joint frailty models.*

Description

Plots values of the difference of two Cross-Validated Prognosis Observed Loss (CVPOL) computed with two joint frailty models. Confidence intervals are allowed.

Usage

```
## S3 method for class 'Diffepoce'
plot(x, conf.bands=TRUE, Xlab = "Time", Ylab =
"EPOCE difference" , ...)
```

Arguments

x	An object inheriting from `Diffepoce` class.
conf.bands	Logical value. Determines whether confidence intervals will be plotted. The default is FALSE.
Xlab	Label of x-axis. Default is '"Time"'
Ylab	Label of y-axis. Default is '"EPOCE difference"'
...	Other unused arguments.

Value

Print one plot with one curve and its confidence interval.

See Also

[Diffepoce]

---

plot.epoce   *Plot values of estimators of the Expected Prognostic Observed Cross-Entropy (EPOCE).*

Description

Plots values of estimators MPOL and CVPOL for evaluating EPOCE. No confidence interval.

Usage

```
## S3 method for class 'epoce'
plot(x, type, pos.legend="topright", cex.legend=0.7,
Xlab="Time",Ylab="Epoce", ...)
```

Arguments

x	An object inheriting from epoce class
type	Type of estimator to plot. If new dataset was used only mpol can be plotted (″mpol″), otherwise mpol and cvpol can be plotted (″mpol″ and ″cvpol″, default is ″cvpol″).
pos.legend	The location of the legend can be specified by setting this argument to a single keyword from the list '"bottomright"', '"bottom"', '"bottomleft"', '"left"', '"topleft"', '"top"', '"topright"', '"right"' and '"center"'. The default is '"topright"'.
cex.legend	size of the legend. Default is 0.7.
Xlab	Label of x-axis. Default is '"Time"'
Ylab	Label of y-axis. Default is '"Epoce"'
...	Other unused arguments.

Value

Print a curve of the estimator of EPOCE using time points defined in epoce.

See Also

epoce

plot.frailtyPenal	*Plot Method for a Shared frailty model.*

Description

Plots estimated baseline survival and hazard functions from an object of class 'frailtyPenal'. Confidence bands are allowed.

Usage

```
## S3 method for class 'frailtyPenal'
plot(x, type.plot = "Hazard", conf.bands=TRUE,
pos.legend = "topright", cex.legend=0.7, main, color=2, median=TRUE, Xlab = "Time", Ylab
= "Hazard function", ...)
```

Arguments

x	A shared frailty model, i.e. a frailtyPenal class object (output from calling frailtyPenal function).
type.plot	a character string specifying the type of curve. Possible value are "Hazard", or "Survival". The default is "Hazard". Only the first letters are required, e.g "Haz", "Su"
conf.bands	Logical value. Determines whether confidence bands will be plotted. The default is to do so.

pos.legend	The location of the legend can be specified by setting this argument to a single keyword from the list '"bottomright"', '"bottom"', '"bottomleft"', '"left"', '"topleft"', '"top"', '"topright"', '"right"' and '"center"'. The default is '"topright"'
cex.legend	character expansion factor *relative* to current 'par("cex")'. Default is 0.7
main	title of plot
color	color of the curve (integer)
median	Logical value. Determines whether survival median will be plotted. Default is TRUE.
Xlab	Label of x-axis. Default is '"Time"'
Ylab	Label of y-axis. Default is '"Hazard function"'
...	other unused arguments

Value

Print a plot of a shared frailty model.

See Also

## End(Not run)
```

---

plot.jointNestedPenal   *Plot method for a joint nested frailty model.*

Description

Plots estimated baseline survival and hazard functions of a joint nested frailty model (output from an object of class 'jointNestedPenal' for joint nested frailty models) for each type of event (terminal or recurrent). Confidence bands are allowed.

Usage

```
## S3 method for class 'jointNestedPenal'
plot(x, event = "Both", type.plot = "Hazard",
conf.bands = FALSE, pos.legend="topright", cex.legend = 0.7, ylim, main,
color = 2, median=TRUE, Xlab = "Time", Ylab = "Hazard function", ...)
```

Arguments

x	A joint nested model, i.e. an object of class jointNestedPenal for joint nested frailty model (output from calling frailtyPenal function).
event	a character string specifying the type of curve. Possible value are "Terminal", "Recurrent", or "Both". The default is "Both".
type.plot	a character string specifying the type of curve. Possible value are "Hazard", or "Survival". The default is "Hazard". Only the first letters are required, e.g "Haz", "Su"
conf.bands	logical value. Determines whether confidence bands will be plotted. The default is to do so.
pos.legend	The location of the legend can be specified by setting this argument to a single keyword from the list '"bottomright"', '"bottom"', '"bottomleft"', '"left"', '"topleft"', '"top"', '"topright"', '"right"' and '"center"'. The default is '"topright"'
cex.legend	character expansion factor *relative* to current 'par("cex")'. Default is 0.7
ylim	y-axis limits
main	plot title
color	curve color (integer)
median	Logical value. Determines whether survival median will be plotted. Default is TRUE.
Xlab	Label of x-axis. Default is '"Time"'
Ylab	Label of y-axis. Default is '"Hazard function"'
...	other unused arguments

Value

Print a plot of the baseline survival or hazard functions for each type of event or both with the confidence bands or not (conf.bands argument)

plot.jointPenal   *Plot Method for a Joint frailty model.*

Description

Plots estimated baseline survival and hazard functions of a joint frailty model (output from an object of class 'JointPenal' for joint frailty models) for each type of event (terminal or recurrent). Confidence bands are allowed.

Usage

```
## S3 method for class 'jointPenal'
plot(x, event = "Both", type.plot = "Hazard", conf.bands
= FALSE, pos.legend="topright", cex.legend = 0.7, ylim, main, color = 2, median=TRUE,
Xlab = "Time", Ylab = "Hazard function", ...)
```

Arguments

x	A joint model, i.e. an object of class frailtyPenal for Joint frailty model (output from calling frailtyPenal function).
event	a character string specifying the type of curve. Possible value are "Terminal", "Recurrent", or "Both". The default is "Both".
type.plot	a character string specifying the type of curve. Possible value are "Hazard", or "Survival". The default is "Hazard". Only the first letters are required, e.g "Haz", "Su"
conf.bands	logical value. Determines whether confidence bands will be plotted. The default is to do so.
pos.legend	The location of the legend can be specified by setting this argument to a single keyword from the list '"bottomright"', '"bottom"', '"bottomleft"', '"left"', '"topleft"', '"top"', '"topright"', '"right"' and '"center"'. The default is '"topright"'
cex.legend	character expansion factor *relative* to current 'par("cex")'. Default is 0.7
ylim	y-axis limits
main	plot title
color	curve color (integer)
median	Logical value. Determines whether survival median will be plotted. Default is TRUE.
Xlab	Label of x-axis. Default is '"Time"'
Ylab	Label of y-axis. Default is '"Hazard function"'
...	other unused arguments

Value

Print a plot of the baseline survival or hazard functions for each type of event or both with the confidence bands or not (conf.bands argument)

See Also

---

plot.jointSurroMed   *Plot Method for a joint surrogate mediation analysis model.*

Description

Plots the estimated functions associated with the mediation analysis, i.e. $g(s)$, $R(t)$ as well as the natural direct, indirect and total effects. An option to plot the confidence bands of the function $g(s)$ is available. This option is also implemented for the confidence bands of the functions $R(t)$ and of the natural effects if these confidence bands are available.

Usage

```
## S3 method for class 'jointSurroMed'
plot(x,plot.mediation="All",type.plot="Hazard",
conf.bands=TRUE,endpoint=2,
legend.pos = "topleft",...)
```

Arguments

x	An object of class jointSurroMed from a joint surrogate model with a mediation analysis for longitudinal outcome and a terminal event, i.e., an output from calling jointSurroPenal function with the option 'mediation' set to TRUE.
plot.mediation	A character string specifying the desired plot. Possible values are "All", "g","Rt" or "Effects". The default is "All" which displays all three plots.
type.plot	A character string specifying the type of curve for the baseline hazards functions. Possible value are "Hazard", or "Survival".
conf.bands	Logical value. Determines whether confidence bands should be plotted. The default is to do so if the confidence bands are available.
endpoint	An integer specifying for which endpoint should the baseline curves be plotted. Possible values are 0 for the surrogate endpoint only and 1 for the final endpoint or 2 for both. Default is 2.

legend.pos	The location of the legend can be specified by setting this argument to a single keyword from the list '"bottomright"', '"bottom"', '"bottomleft"', '"left"', '"topleft"', '"top"', '"topright"', '"right"' and '"center"'. The default is '"topleft"'
...	other unused arguments.

Value

Print one or several plots for the mediation analysis of a joint surrogate model

See Also

jointSurroPenal

---

plot.jointSurroPenal	*Plot Method for the one-step Joint surrogate model for the evaluation of a canditate surrogate endpoint.*

Description

Plots estimated baseline survival and hazard functions for the surrogate endpoint and the true endpoint from an object of class 'jointSurroPenal'. Confidence bands are allowed.

Usage

```
## S3 method for class 'jointSurroPenal'
plot(x, type.plot = "Hazard", conf.bands=TRUE,
pos.legend = "topright", cex.legend=0.7, main, Xlab = "Time",
Ylab = "Baseline hazard function", median = TRUE, xmin = 0, xmax = NULL,
ylim = c(0,1), endpoint = 2, scale = 1, ...)
```

Arguments

x	An object inheriting from jointSurroPenal class (output from calling the function jointSurroPenal).
type.plot	A character string specifying the type of curve. Possible value are "Hazard", or "Survival". The default is "Hazard". Only the first letters are required, e.g "Haz", "Su".
conf.bands	Logical value. Determines whether confidence bands will be plotted. The default is to do so.
pos.legend	The location of the legend can be specified by setting this argument to a single keyword from the list '"bottomright"', '"bottom"', '"bottomleft"', '"left"', '"topleft"', '"top"', '"topright"', '"right"' and '"center"'. The default is '"topright"'.
cex.legend	Character expansion factor *relative* to current 'par("cex")'. Default is 0.7.
main	Title of plot.
Xlab	Label of x-axis. Default is '"Time"'.

Ylab	Label of y-axis. Default is '"Baseline hazard function"'.
median	Logical value. Determines whether survival median will be plotted. Default is TRUE.
xmin	Minimum value for x-axis, the default is 0.
xmax	Maximum value for x-axis, the default is NULL.
ylim	Range of y-axis. Default is from 0 to 1.
endpoint	A binary that indicates the endpoint to represent. 0 for the surrogate endpoint, 1 for the true endpoint, and 2 for both surrogate endpoint and true endpoint. The default is 2.
scale	A numeric that allows to rescale (by multiplication) the survival times. If no change is need the argument is set to 1, the default value. eg: 1/365 aims to convert days to years .
...	other unused arguments.

Value

Print a plot of the baseline survival or hazard functions for each type of event or both with the confidence bands or not (conf.bands argument)

See Also

jointSurroPenal, jointSurroCopPenal

Examples

```
## Not run:

###--- Joint surrogate model ---###
###---evaluation of surrogate endpoints---###

data(dataOvarian)
joint.surro.ovar <- jointSurroPenal(data = dataOvarian, n.knots = 8,
                init.kappa = c(2000,1000), indicator.alpha = 0,
                nb.mc = 200, scale = 1/365)

# Baseline Hazards fonctions for both the surrogate endpoint
# and the true endpoint
plot(joint.surro.ovar,endpoint = 2,type.plot = "Haz", conf.bands = T)

# Baseline survival fonctions for both the surrogate endpoint

```

```
## End(Not run)
```

---

plot.jointSurroPenalloocv

Plot of trials leave-one-out crossvalidation Outputs from the one-step Joint surrogate model for evaluating a canditate surrogate endpoint.

Description

Plot of trials leave-one-out crossvalidation Outputs for evaluating the joint surrogate model

Usage

```
## S3 method for class 'jointSurroPenalloocv'
plot(x, unusedtrial = NULL, xleg = "bottomleft",
yleg = NULL, main = NULL, xlab = "Trials",
ylab = "Log Hazard ratio of the true endpoint",
legend = c("Beta observed", "Beta predict"), ...)
```

Arguments

x	An object inherent from the jointSurroPenalloocv Class
unusedtrial	Vector of unconsidered trials, may be due to the fact that the predicted treatment effects on true endpoint have an outlier. In this case, one can drop from the data the trials with very hight absolute predicted value
xleg	X-coordinate for the location of the legend.
yleg	Y-coordinate for the location of the legend, the default is NULL
main	An overall title for the plot: see title.
xlab	A title for the x axis: see title.
ylab	A title for the y axis: see title.
legend	A vector of characters string of length >= 1 to appear in the legend
...	other unused arguments.

Value

This function displays the boxplots corresponding to the number of trials in the dataset. Each boxplot includes 3 elements corresponding to the predicted treatment effect on true endpoint with the prediction interval. The circles inside or outside the boxplot represent the observed treatment effects on true endpoint. For each trial with convergence issues or outliers, the boxplot is replaced by a dash. In this case, we display in the title of the figure a vector of these trials, if argument main is set to NULL. The function returns the list of unused trials.

plot.longiPenal   *Plot Method for a joint model for longitudinal data and a terminal*
                            event.

Description

Plots estimated baseline survival and hazard functions for a terminal outcome from an object of class 'longiPenal'. Confidence bands are allowed.

Usage

```
## S3 method for class 'longiPenal'
plot(x, type.plot = "Hazard", conf.bands=TRUE,
pos.legend= "topright", cex.legend=0.7, main, color, median=TRUE, Xlab = "Time", Ylab =
"Hazard function", ...)
```

Arguments

x	A joint model for longitudinal outcome and a terminal event, i.e. a `longiPenal` class object (output from calling `longiPenal` function).
type.plot	a character string specifying the type of curve for the terminal event. Possible value are "Hazard", or "Survival". The default is "Hazard". Only the first words are required, e.g "Haz", "Su"
conf.bands	Logical value. Determines whether confidence bands will be plotted. The default is to do so.
pos.legend	The location of the legend can be specified by setting this argument to a single keyword from the list '"bottomright"', '"bottom"', '"bottomleft"', '"left"', '"topleft"', '"top"', '"topright"', '"right"' and '"center"'. The default is '"topright"'
cex.legend	character expansion factor *relative* to current 'par("cex")'. Default is 0.7
main	title of plot
color	color of the curve (integer)
median	Logical value. Determines whether survival median will be plotted. Default is TRUE.
Xlab	Label of x-axis. Default is '"Time"'
Ylab	Label of y-axis. Default is '"Hazard function"'
...	other unused arguments

Value

Print a plot for the terminal event of the joint model for a longitudinal and survival data.

plot.multivPenal   *Plot Method for a multivariate frailty model.*

Description

Plots of estimated baseline survival and hazard functions of a multivariate frailty model (output from
an object of class 'multivPenal' for multivariate frailty models) for each type of event (recurrent,
terminal and second recurrent). Confidence intervals are allowed.

Usage

```
## S3 method for class 'multivPenal'
plot(x, event = "Both", type.plot = "Hazard",
conf.bands = FALSE, pos.legend = "topright", cex.legend = 0.7, ylim, main,
color1="red", color2="blue", colorEnd="green", median=TRUE, Xlab = "Time",
Ylab = "Hazard function", ...)
```

Arguments

x	A joint multivariate model, i.e. an object of class multivPenal (output from calling multivPenal function).
event	a character string specifying the type of outcome. Possible value are "Terminal", "Recurrent", "Recurrent2", or "Both". The default is "Both".
type.plot	a character string specifying the type of curve. Possible value are "Hazard", or "Survival". The default is "Hazard". Only the first words are required, e.g "Haz", "Su"

conf.bands	logical value. Determines whether confidence intervals will be plotted. The default is to do so.
pos.legend	The location of the legend can be specified by setting this argument to a single keyword from the list '"bottomright"', '"bottom"', '"bottomleft"', '"left"', '"topleft"', '"top"', '"topright"', '"right"' and '"center"'. The default is '"topright"'
cex.legend	character expansion factor *relative* to current 'par("cex")'. Default is 0.7
ylim	y-axis limits
main	plot title
color1	curve color for recurrent event of type 1 (integer or color name in quotation marks)
color2	curve color for recurrent event of type 2 (integer or color name in quotation marks)
colorEnd	curve color for terminal event (integer or color name in quotation marks)
median	Logical value. Determines whether survival median will be plotted. Default is TRUE.
Xlab	Label of x-axis. Default is '"Time"'
Ylab	Label of y-axis. Default is '"Hazard function"'
...	Other graphical parameters

Value

Print a plot of the baseline survival or hazard functions for each type of event or both with the confidence intervals or not (conf.bands argument)

## S3 method for class 'nestedPenal'
plot(x, type.plot="Hazard", conf.bands=TRUE,
pos.legend="topright", cex.legend=0.7, main, color=2, median=TRUE, Xlab = "Time", Ylab =
"Hazard function", ...)
```

Arguments

x	A nested model, i.e. an object of class `frailtyPenal` for Nested frailty models (output from calling `frailtyPenal` function).
type.plot	a character string specifying the type of curve. Possible value are "Hazard", or "Survival". The default is "Hazard". Only the first words are required, e.g "Haz", "Su"
conf.bands	logical value. Determines whether confidence bands will be plotted. The default is to do so.
pos.legend	The location of the legend can be specified by setting this argument to a single keyword from the list '"bottomright"', '"bottom"', '"bottomleft"', '"left"', '"topleft"', '"top"', '"topright"', '"right"' and '"center"'. The default is '"topright"'
cex.legend	character expansion factor *relative* to current 'par("cex")'. Default is 0.7
main	plot title
color	curve color (integer)
median	Logical value. Determines whether survival median will be plotted. Default is TRUE.
Xlab	Label of x-axis. Default is '"Time"'
Ylab	Label of y-axis. Default is '"Hazard function"'
...	Other graphical parameters like those in [plot.frailtyPenal](#)

Value

Print a plot of the baseline survival or hazard functions with the confidence bands or not (conf.bands argument)

## End(Not run)
```

---

plot.predFrailty *Plot predictions using a Cox or a shared frailty model.*

Description

Plots predicted probabilities of event. Confidence intervals are allowed.

Usage

```
## S3 method for class 'predFrailty'
plot(x, conf.bands=FALSE, pos.legend="topright",
cex.legend=0.7, ylim=c(0,1), Xlab = "Time t", Ylab, ...)
```

Arguments

x	An object from the 'prediction' function, i.e. a `predFrailty` class object.
conf.bands	Logical value. Determines whether confidence intervals will be plotted. The default is FALSE.
pos.legend	The location of the legend can be specified by setting this argument to a single keyword from the list '"bottomright"', '"bottom"', '"bottomleft"', '"left"', '"topleft"', '"top"', '"topright"', '"right"' and '"center"'. The default is '"topright"'.
cex.legend	size of the legend. Default is 0.7.
ylim	range of y-axis. Default is from 0 to 1.
Xlab	Label of x-axis. Default is '"Time t"'
Ylab	Label of y-axis.
...	Other unused arguments.

Value

Print one plot with as many curves as the number of profiles.

---

plot.predJoint *Plot predictions using a joint frailty model.*

Description

Plots predicted probabilities of terminal event. Confidence intervals are allowed.

Usage

```
## S3 method for class 'predJoint'
plot(x, conf.bands=FALSE,
relapses=TRUE,pos.legend="topright", cex.legend=0.7, ylim=c(0,1), Xlab =
"Time t", Ylab = "Prediction probability of event", ...)
```

Arguments

x	An object from the 'prediction' function, more generaly a `predJoint` class object.
conf.bands	Logical value. Determines whether confidence intervals will be plotted. The default is FALSE.
relapses	Logical value. Determines whether observed recurrent events will be plotted. The default is TRUE.
pos.legend	The location of the legend can be specified by setting this argument to a single keyword from the list '"bottomright"', '"bottom"', '"bottomleft"', '"left"', '"topleft"', '"top"', '"topright"', '"right"' and '"center"'. The default is '"topright"'
cex.legend	size of the legend. Default is 0.7
ylim	range of y-axis. Default is from 0 to 1
Xlab	Label of x-axis. Default is '"Time t"'
Ylab	Label of y-axis. Default is '"Prediction probability of event"'
...	Other unused arguments

Value

Print as many plots as the number of subjects.

---

plot.predLongi	*Plot predictions using a joint model for longitudinal data and a terminal event or a trivariate joint model for longitudinal data, recurrent events and a terminal event.*

Description

Plots predicted probabilities of the event. Confidence intervals are allowed.

Usage

```
## S3 method for class 'predLongi'
plot(x, conf.bands=FALSE, pos.legend="topright",
cex.legend=0.7, ylim=c(0,1), Xlab = "Time t", Ylab, ...)
```

Arguments

x	An object inheriting from `predLongi`.
conf.bands	Logical value. Determines whether confidence intervals will be plotted. The default is FALSE.
pos.legend	The location of the legend can be specified by setting this argument to a single keyword from the list '"bottomright"', '"bottom"', '"bottomleft"', '"left"', '"topleft"', '"top"', '"topright"', '"right"' and '"center"'. The default is '"topright"'.
cex.legend	size of the legend. Default is 0.7.

ylim	range of y-axis. Default is from 0 to 1.
Xlab	Label of x-axis. Default is '"Time t"'
Ylab	Label of y-axis.
...	Other unused arguments.

Value

Print one plot with as many curves as the number of profiles.

| plot.trivPenal | *Plot Method for a trivariate joint model for longitudinal data, recurrent events and a terminal event.* |

Description

Plots estimated baseline survival and hazard functions of a joint model (output from an object of class 'trivPenal') for each type of event (terminal or recurrent). Confidence bands are allowed.

Usage

plotTreatPredJointSurro

Plot of the prediction of the treatment effect on the true endpoint and the STE

Description

Plot the prediction of the treatment effect on the true endpoint based on the observed treatment effect on the surrogate endpoint, with the prediction interval: results from the one-step Joint surrogate model for evaluating a canditate surrogate endpoint. The graphic also includes vertical lines that cut the x axis to the values of ste. A hatched rectagle/zone indicates the values of β_S that predict a non zeto β_T , according to the number of value for STE and the shape of the upper confidence limit for the prediction model.

Usage

```
plotTreatPredJointSurro(
  object,
  from = -3,
  to = 2,
  type = "Coef",
  var.used = "error.estim",
  alpha. = 0.05,

)
```

Arguments

object	An object inheriting from jointSurroPenal class (output from calling the function jointSurroPenal).
from	The range (with to) over which the function will be plotted. The default is from −2 to 2
to	The range (with from) over which the function will be plotted. The default is from −2 to 2
type	The type of graphic, "Coef" for the log HR or "HR" for hazard ratio. If set to HR, the arguments from and to must take positive values. The default is "Coef".
var.used	This argument can take two values. The first one is "error.estim" and indicates if the prediction error take into account the estimation error of the estimates of the parameters. If the estimates are supposed to be known or if the dataset includes a high number of trials with a high number of subject per trial, value No.error can be used. The default is error.estim (highly recommended).
alpha.	The confidence level for the prediction interval. The default is 0.05
n	An integer that indicates the number of values for β_S . The default is 1000.
lty	The line type. Line types can either be specified as an integer (0=blank, 1=solid (default), 2=dashed, 3=dotted, 4=dotdash, 5=longdash, 6=twodash) or as one of the character strings "blank", "solid", "dashed", "dotted", "dotdash","longdash", or "twodash", where "blank" uses "invisible lines" (i.e., does not draw them). The default is 2.
d	The desired number of digits after the decimal point for parameters and confidence intervals. Default of 3 digits is used.
colCI	The color used to display the confidence interval.
xlab	A title for the x axis.

ylab	A title for the y axis.
pred.int.use	A character string that indicates the bound of the prediction interval to use to compute the STE. Possible values are up for the upper bound (the default) or lw for the lower bound. up when we have a protective treatment effect and lw when we have a deleterious treatment effect.
main	Title of the graphics
add.accept.area.betaS	
	A boolean that indicates if the plot should add acceptance area for β_S that predict a nonzero β_T . The default is TRUE
ybottom	A scalar for the left y bottom position of the rectangle on the x-axis associated with acceptable value for β_S to predict a non zero β_T . The default is -0.05.
ytop	A scalar for the top right y position of the rectangle on the x-axis associated with acceptable value for β_S to predict a non zero β_T . The default is 0.05.
density	The density of shading lines, in lines per inch. The default value of 'NULL' means that no shading lines are drawn. A zero value of 'density' means no shading lines whereas negative values (and 'NA') suppress shading (and so allow color filling). The default is 20
angle	Angle (in degrees) of the shading lines. The default is 45
legend.show	A boolean that indicates if the legend should be displayed
leg.x	The x co-ordinate to be used to position the legend.
leg.y	The y co-ordinate to be used to position the legend. The default is 4
legend	A character or expression vector of length >= 1 to appear in the legend
leg.text.col	The color used for the legend text. The default is black.
leg.lty	The line type, width and color for the legend box (if bty = "o").
leg.pch	= The plotting symbols appearing in the legend, as numeric vector or a vector of 1-character strings (see points). Unlike points, this can all be specified as a single multi-character string. Must be specified for symbol drawing.
leg.bg	The background color for the legend box. (Note that this is only used if bty != "n".)
leg.bty	The type of box to be drawn around the legend. The allowed values are "o" (the default) and "n".
leg.cex	Character expansion factor relative to current par("cex"). Used for text as defined in legend.
...	other unused arguments

Value

For a considered treatment effects on the surrogate enpoint, plot the associated treatment effects on the true endpoint predicted from the joint surrogate model with the prediction interval.

predict.jointSurroPenal

> *S3method predict for the one-step Joint surrogate models for the evaluation of a canditate surrogate endpoint.*

Description

Predict the treatment effect on the true endpoint (β_T), based on the treatment effect observed on the surrogate endpoint (β_S).

Usage

```
## S3 method for class 'jointSurroPenal'
predict(object, datapred = NULL, betaS.obs = NULL,
betaT.obs = NULL, ntrial0 = NULL, var.used = "error.estim", alpha. = 0.05,
dec = 3, colCI = "red", from = -2, to = 2, type = "Coef", ...)
```

Arguments

object	An object inheriting from jointSurroPenal class (output from calling the function jointSurroPenal or jointSurroCopPenal).
datapred	Dataset to use for the prediction. If this argument is specified, the data structure must be the same as the parameter data in the function [jointSurroPenal] or [jointSurroCopPenal]. However, if observation on the true endpoint are not available, columns timeT and statusT can be absent. In this case, the β_S are calculated using Cox proportional hazards models.
betaS.obs	Observed treatment effect on the surrogate endpoint, to use for the prediction of the treatment effect on the true endpoint. If not null, this value is used for prediction instead of datapred. The default is NULL.
betaT.obs	Observed treatment effect on the true endpoint. Used to assess the prediction if not null. The defaut is NULL.
ntrial0	Number of subjects include in the new trial. Required if betaS.obs is not null. The default is NULL.
var.used	This argument can take two values. The first one is "error.estim" and indicates if the prediction error take into account the estimation error of the estimates of the parameters. If the estimates are supposed to be known or if the dataset includes a high number of trials with a high number of subject per trial, value No.error can be used. The default is error.estim (highly recommended).
alpha.	The confidence level for the prediction interval. The default is 0.05
dec	The desired number of digits after the decimal point for parameters and confidence intervals. Default of 3 digits is used.
colCI	The color used to display the confidence interval.
from	The range (with to) over which the function will be plotted. The default is from -2 to 2

to	The range (with `from`) over which the function will be plotted. The default is `from -2 to 2`
type	The type of graphic, `"Coef"` for the `log` HR or `"HR"` for hazard ratio. If set to HR, the arguments `from` and `to` must take positive values. The default is `"Coef"`.
...	other unused arguments. See the function ([plotTreatPredJointSurro](#))

Details

Prediction is based on the formulas described in (Burzikwosky *et al.*, 2006). We do not consider the case in which the prediction take into account estimation error on the estimate of the treatment effect on the surrogate endpoint in the new trial.

Value

Returns and display a dataframe including for each trial the number of included subjects (if available), the observed treatment effect on surrogate endpoint, the observed treatment effect on true endpoint (if available) and the predicted treatment effect on true enpoint with the associated prediction intervals. If the observe treatment effect on true endpoint (if available) is included into the prediction interval, the last columns contains "*". This function also produces a plot of predicted treatment effects on the true endpoint according to the given values of the treatment effects on the surrogate endpoint, with the prediction intervals.

prediction	*Prediction probabilities for Cox proportional hazard, Shared, Joint frailty models, Joint models for longitudinal data and a terminal event and Trivariate joint model for longitudinal data, recurrent events and a terminal event (linear and non-linear).*

Description

For Cox proportional hazard model

A predictive probability of event between t and horizon time t+w, with w the window of prediction.

$$P(t, t+w) = \frac{S_i(t) - S_i(t+w)}{S_i(t)} = 1 - \left(\frac{S_0(t+w)}{S_0(t)} \right)^{\exp(\beta' Z_i)}$$

For Gamma Shared Frailty model for clustered (not recurrent) events

Two kinds of predictive probabilities can be calculated:

- a conditional predictive probability of event between t and horizon time t+w, i.e. given a specific group

$$P^{cond}(t, t+w) = \frac{S_{ij}(t|u_i) - S_{ij}(t+w|u_i)}{S_{ij}(t|u_i)} = 1 - \left(\frac{S_0(t+w)}{S_0(t)} \right)^{u_i \exp(\beta' Z_{ij})}$$

- a marginal predictive probability of event between t and horizon time t+w, i.e. averaged over the population

$$P^{marg}(t, t+w) = 1 - \left(\frac{1 + \theta H_0(t) \exp(\beta' Z_{ij})}{1 + \theta H_0(t+w) \exp(\beta' Z_{ij})} \right)^{1/\theta}$$

For Gaussian Shared Frailty model for clustered (not recurrent) events

Two kinds of predictive probabilities can be calculated:

- a conditional predictive probability of event between t and horizon time t+w, i.e. given a specific group and given a specific Gaussian random effect η

$$P^{cond}(t, t+w) = \frac{S_{ij}(t|\eta_i) - S_{ij}(t+w|\eta_i)}{S_{ij}(t|\eta_i)} = 1 - \left(\frac{S_0(t+w)}{S_0(t)} \right)^{\exp(\eta_i + \beta' Z_{ij})}$$

- a marginal predictive probability of event between t and horizon time t+w, i.e. averaged over the population

$$P^{marg}(t, t+w) = \frac{\int_{-\infty}^{+\infty} (S_{ij}(t|\eta_i) - S_{ij}(t+w|\eta_i)) g(\eta) d\eta}{\int_{-\infty}^{+\infty} S_{ij}(t) g(\eta) d\eta}$$

For Gamma Shared Frailty model for recurrent events

Two kinds of predictive probabilities can be calculated:

- A marginal predictive probability of event between t and horizon time t+w, i.e. averaged over the population.

$$P^{marg}(t, t+w) = \frac{\int_0^{+\infty} (S_{i(J+1)}(t|u_i) - S_{ij}(t+w|u_i)) \cdot (u_i)^J S_{ij}(X_{iJ}|u_i) g(u) du}{\int_0^{+\infty} S_{i(J+1)}(t|u_i)(u_i)^J S_{i(J+1)}(X_{iJ}|u_i)) g(u) du}$$

- a conditional predictive probability of event between t and horizon time t+w, i.e. given a specific individual.

This prediction method is the same as the conditional gamma prediction method applied for clustered events (see formula

$$P^{cond}$$

before).

For Gaussian Shared Frailty model for recurrent events

Two kinds of predictive probabilities can be calculated:

- A marginal predictive probability of event between t and horizon time t+w, i.e. averaged over the population.

$$P^{marg}(t, t+w) = \frac{\int_0^{+\infty} (S_{i(J+1)}(t|\eta_i) - S_{ij}(t+w|\eta_i)) \cdot \exp(J\eta_i) S_{ij}(X_{iJ}|\eta_i) g(\eta) d\eta}{\int_0^{+\infty} S_{i(J+1)}(t|\eta_i) \exp(J\eta_i) S_{i(J+1)}(X_{iJ}|\eta_i)) g(\eta) d\eta}$$

- a conditional predictive probability of event between t and horizon time t+w, i.e. given a specific individual.

This prediction method is the same as the conditional Gaussian prediction method applied for clustered events (see formula

$$P^{cond}$$

before).

It is possible to compute all these predictions in two ways on a scale of times : - either you want a cumulative probability of developing the event between t and t+w (with t fixed, but with a varying window of prediction w); - either you want at a specific time the probability to develop the event in the next w (ie, for a varying prediction time t, but for a fixed window of prediction). See Details.

For Joint Frailty model

Prediction for two types of event can be calculated : for a terminal event or for a new recurrent event, knowing patient's characteristics.

- Prediction of death knowing patients' characteristics :

It is to predict the probability of death in a specific time window given the history of patient i before the time of prediction t. The history $H_i^{J,l}$, $(l = 1, 2)$ is the information on covariates before time t, but also the number of recurrences and the time of occurences. Three types of marginal probabilities are computed:

- a prediction of death between t and t+w given that the patient had exactly J recurrences $(H_i^{J,1})$ before t

$$P^1(t, t+w) = P(D_i \leq t+w | D_i > t, H_i^{J,1}) = \frac{\int_0^\infty [S_i^D(t) - S_i^D(t+w)](u_i)^J S_{i(J+1)}^R(t)g(u)du_i}{\int_0^\infty S_i^D(t)(u_i)^J S_{i(J+1)}^R(t)g(u)du_i}$$

- a prediction of death between t and t+w given that the patient had at least J recurrences $(H_i^{J,2})$ before t

$$P^2(t, t+w) = P(D_i \leq t+w | D_i > t, H_i^{J,2}) = \frac{\int_0^\infty [S_i^D(t) - S_i^D(t+w)](u_i)^J S_{iJ}^R(X_{iJ})g(u)du_i}{\int_0^\infty S_i^D(t)(u_i)^J S_{iJ}^R(X_{iJ})g(u)du_i}$$

- a prediction of death between t and t+w considering the recurrence history only in the parameters estimation. It corresponds to the average probability of death between t and t+w for a patient with these given characteristics.

$$P^3(t, t+w) = P(D_i \leq t+w | D_i > t) = \frac{\int_0^\infty [S_i^D(t) - S_i^D(t+w)]g(u)du_i}{\int_0^\infty S_i^D(t)g(u)du_i}$$

- Prediction of risk of a new recurrent event knowing patients' characteristics :

It is to predict the probability of a new recurrent event in a specific time window given the history of patient i before the time of prediction t. The history H_i^J is the information on covariates before time t, but also the number of recurrences and the time of occurences. The marginal probability computed is a prediction of a new recurrent event between t and t+w given that the patient had exactly J recurrences (H_i^J) before t:

$$P^R(t, t+w) = P(X_{i(j+1)} \leq t+w | X_{i(j+1)} > t, D_i > t, H_i^J) =$$

$$\frac{\int_0^\infty [S^R_{i(J+1)}(t) - S^R_{i(J+1)}(t+w)] S^D_i(t)(u_i)^J S^R_{i(J+1)}(X_{ij}) g(u) du_i}{\int_0^\infty S^R_{i(J+1)}(t) S^D_i(t)(u_i)^J S^R_{i(J+1)}(X_{ij}) g(u) du_i}$$

It is possible to compute all these predictions in two ways : - either you want a cumulative probability of developing the event between t and t+w (with t fixed, but with a varying window of prediction w); - either you want at a specific time the probability to develop the event in the next w (ie, for a varying prediction time t, but for a fixed window of prediction). See Details.

With Gaussian frailties (η), the same expressions are used but with $u_i{}^J$ replaced by $\exp(J\eta_i)$ and $g(\eta)$ corresponds to the Gaussian distribution.

For Joint Nested Frailty models

Prediction of the probability of developing a terminal event between t and t+w for subject i who survived by time t based on the visiting and disease histories of their own and other family members observed by time t.

Let $(Y^R_{fi}(t))$ be the history of subject i in family f, before time t, which includes all the recurrent events and covariate information. For disease history, let $T^D_{fi}(t) = min(T_{fi}, t)$ be the observed time to an event before t ; $\delta^D_{fi}(t)$ the disease indicator by time t and $X^D_{fi}(t)$ the covariate information observed up to time t. We define the family history of subject i in family f by

$$H_{f(-i)}(t) = \{Y^R_{fl}(t), T^D_{fl}(t), \delta^D_{fl}(t), X^D_{fl}(t), \forall l \in \{1, ..., i-1, i+1, ..., m_f\}\}$$

which includes the visiting and disease history of all subjects except for subject i in family f as well as their covariate information by time t.

The prediction probability can be written as :

$$P(T^D_{fi} < t+s | T^D_{fi} > t, Y_i(t), H_{(f-i)}(t)) =$$

$$\frac{\int \int P(t < T^D_{fi} < t+s | X^D_{fi}, \omega_{fi}) P(Y_i(t) | X^R_{fi}(t), \omega_i) P(H_{f(-i)}(t) | X_{f(-i)}(t), \omega_{fi}) g_{ui} g_{\omega f}}{\int \int P(T^D_{fi} > t | X^D_{fi}, \omega_{fi}) P(Y_i(t) | X^R_{fi}(t), \omega_i) P(H_{f(-i)}(t) | X_{f(-i)}(t), \omega_{fi}) g_{ui} g_{\omega f}}$$

For Joint models for longitudinal data and a terminal event

The predicted probabilities are calculated in a specific time window given the history of biomarker measurements before the time of prediction t ($\mathcal{Y}_i(t)$). The probabilities are conditional also on covariates before time t and that the subject was at risk at t. The marginal predicted probability of the terminal event is

$$P(t, t+w) = P(D_i \le t+w | D_i > t, \mathcal{Y}_i(t)) = \frac{\int_0^\infty [S^D_i(t) - S^D_i(t+w)] f(\mathcal{Y}_i(t) | \boldsymbol{X}_{Li}, \boldsymbol{b}_i) f(\boldsymbol{b}_i) d\boldsymbol{b}_i}{\int_0^\infty S^D_i(t) f(\mathcal{Y}_i(t) | \boldsymbol{X}_{Li}, \boldsymbol{b}_i) f(\boldsymbol{b}_i) d\boldsymbol{b}_i}$$

These probabilities can be calculated in several time points with fixed time of prediction t and varying window w or with fixed window w and varying time of prediction t. See Details for an example of how to construct time windows.

For Trivariate joint models for longitudinal data, recurrent events and a terminal event

The predicted probabilities are calculated in a specific time window given the history of biomarker measurements $\mathcal{Y}_i(t)$ and recurrences $H_i^{J,1}$ (complete history of recurrences with known J number of observed events) before the time of prediction t. The probabilities are conditional also on co-variates before time t and that the subject was at risk at t. The marginal predicted probability of the terminal event is

$$
\begin{aligned}
P(t, t+w) \quad &= P(D_i \leq t+w | D_i > t, H_i^{J,1}, \mathcal{Y}_i(t)) \\
&= \frac{\int_0^\infty [S_i^P(t) - S_i^P(t+w)]] \exp(J(v_i + g(t)^\top \boldsymbol{\eta}_R)) S_{i(J+1)}^R(t) f(\mathcal{Y}_i(t) | \boldsymbol{X}_{Li}, \boldsymbol{b}_i) f(\boldsymbol{u}_i) d\boldsymbol{u}_i}{\int_0^\infty S_i^P(t) \exp(J(v_i + g(t)^\top \boldsymbol{\eta}_R)) S_{i(J+1)}^R(t) f(\mathcal{Y}_i(t) | \boldsymbol{X}_{Li}, \boldsymbol{b}_i) f(\boldsymbol{u}_i) d\boldsymbol{u}_i}
\end{aligned}
$$

The biomarker history can be represented using a linear (`trivPenal`) or non-linear mixed-effects model (`trivPenalNL`).

These probabilities can be calculated in several time points with fixed time of prediction t and varying window w or with fixed window w and varying time of prediction t. See Details for an example of how to construct time windows.

Usage

```
prediction(fit, data, data.Longi, t, window, event="Both", conditional =
FALSE, MC.sample=0, individual)
```

Arguments

`fit`	A frailtyPenal, jointPenal, longiPenal, trivPenal or trivPenalNL object.
`data`	Data frame for the prediction. See Details.
`data.Longi`	Data frame for the prediction used for joint models with longitudinal data. See Details.
`t`	Time or vector of times for prediction.
`window`	Window or vector of windows for prediction.
`event`	Only for joint and shared models. The type of event you want to predict : "Terminal" for a terminal event, "Recurrent" for a recurrent event or "Both". Default value is "Both". For joint nested model, only 'Terminal' is allowed. In a shared model, if you want to predict a new recurrent event then the argument "Recurrent" should be use. If you want to predict a new event from clustered data, do not use this option.
`conditional`	Only for prediction method applied on shared models. Provides distinction between the conditional and marginal prediction methods. Default is FALSE.
`MC.sample`	Number of samples used to calculate confidence bands with a Monte-Carlo method (with a maximum of 1000 samples). If MC.sample=0 (default value), no confidence intervals are calculated.
`individual`	Only for joint nested model. Vector of individuals (of the same family) you want to make prediction.

Details

To compute predictions with a prediction time t fixed and a variable window:

```
prediction(fit, datapred, t=10, window=seq(1,10,by=1))
```

Otherwise, you can have a variable prediction time and a fixed window.

```
prediction(fit, datapred, t=seq(10,20,by=1), window=5)
```

Or fix both prediction time t and window.

```
prediction(fit, datapred,
t=10, window=5)
```

The data frame building is an important step. It will contain profiles of patient on which you want to do predictions. To make predictions on a Cox proportional hazard or a shared frailty model, only covariates need to be included. You have to distinguish between numerical and categorical variables (factors). If we fit a shared frailty model with two covariates sex (factor) and age (numeric), here is the associated data frame for three profiles of prediction.

```
 datapred <- data.frame(sex=0,age=0) datapred$sex <-
as.factor(datapred$sex) levels(datapred$sex)<- c(1,2) datapred[1,] <-
c(1,40) # man, 40 years old datapred[2,] <- c(2,45) # woman, 45 years old
datapred[3,] <- c(1,60) # man, 60 years old
```

Time-dependent covariates: In the context of time-dependent covariate, the last previous value of the covariate is used before the time t of prediction.

It should be noted, that in a data frame for both marginal and conditional prediction on a shared frailty model for clustered data, the group must be specified. In the case of marginal predictions this can be any number as it does not influence predictions. However, for conditional predictions, the group must be also included in the data set used for the model fitting. The conditional predictions apply the empirical Bayes estimate of the frailty from the specified cluster. Here, three individuals belong to group 5.

```
 datapred <- data.frame(group=0, sex=0,age=0) datapred$sex <-
as.factor(datapred$sex) levels(datapred$sex)<- c(1,2) datapred[1,] <-
c(5,1,40) # man, 40 years old (cluster 5) datapred[2,] <- c(5,2,45) # woman,
45 years old (cluster 5) datapred[3,] <- c(5,1,60) # man, 60 years old
(cluster 5)
```

To use the prediction function on joint frailty models and trivariate joint models, the construction will be a little bit different. In these cases, the prediction for the terminal event takes into account covariates but also history of recurrent event times for a patient. You have to create a data frame with the relapse times, the indicator of event, the cluster variable and the covariates. Relapses occurring after the prediction time may be included but will be ignored for the prediction. A joint model with calendar-timescale need to be fitted with Surv(start,stop,event), relapse times correspond to the "stop" variable and indicators of event correspond to the "event" variable (if event=0, the relapse will not be taken into account). For patients without relapses, all the values of "event" variable

should be set to 0. Finally, the same cluster variable name needs to be in the joint model and in the data frame for predictions ("id" in the following example). For instance, we observe relapses of a disease and fit a joint model adjusted for two covariates sex (1:male 2:female) and chemo (treatment by chemotherapy 1:no 2:yes). We describe 3 different profiles of prediction all treated by chemotherapy: 1) a man with four relapses at 100, 200, 300 and 400 days, 2) a man with only one relapse at 1000 days, 3) a woman without relapse.

```
 datapred <- data.frame(time=0,event=0,id=0,sex=0,chemo=0)
datapred$sex <- as.factor(datapred$sex) levels(datapred$sex) <- c(1,2)
datapred$chemo <- as.factor(datapred$chemo) levels(datapred$chemo) <- c(1,2)
datapred[1,] <- c(100,1,1,1,2) # first relapse of the patient 1 datapred[2,]
<- c(200,1,1,1,2) # second relapse of the patient 1 datapred[3,] <-
c(300,1,1,1,2) # third relapse of the patient 1 datapred[4,] <-
c(400,1,1,1,2) # fourth relapse of the patient 1 datapred[5,] <-
c(1000,1,2,1,2) # one relapse at 1000 days for patient 2 datapred[6,] <-
c(100,0,3,2,2) # patient 3 did not relapse
```

The data can also be the dataset used to fit the joint model. In this case, you will obtain as many prediction rows as patients.

Finally, for the predictions using joint models for longitudinal data and a terminal event and trivariate joint models, a data frame with the history of the biomarker measurements must be provided. It must include data on measurements (values and time points), cluster variable and covariates. Measurements taken after the prediction time may be included but will be ignored for the prediction. The same cluster variable name must be in the data frame, in the data frame used for the joint model and in the data frame with the recurrent event and terminal event times. For instance, we observe two patients and each one had 5 tumor size measurements (patient 1 had an increasing tumor size and patient 2, decreasing). The joint model used for the predictions was adjusted on sex (1: male, 2: female), treatment (1: sequential arm, 2: combined arm), WHO baseline performance status (1: 0 status, 2: 1 status, 3: 2 status) and previous resection of the primate tumor (0: no, 1: yes). The data frame for the biomarker measurements can be:

```
 datapredj_longi <- data.frame(id = 0, year = 0, tumor.size =
0, treatment = 0, age = 0, who.PS = 0, prev.resection = 0)
datapredj_longi$treatment <- as.factor(datapredj_longi$treatment)
levels(datapredj_longi$treatment) <- 1:2 datapredj_longi$age <-
as.factor(datapredj_longi$age) levels(datapredj_longi$age) <- 1:3
datapredj_longi$who.PS <- as.factor(datapredj_longi$who.PS)
levels(datapredj_longi$who.PS) <- 1:3 datapredj_longi$prev.resection <-
as.factor (datapredj_longi$prev.resection)
levels(datapredj_longi$prev.resection) <- 1:2 # patient 1: increasing tumor
size datapredj_longi[1,] <- c(1, 0,1.2 ,2,1,1,1) datapredj_longi[2,] <-
c(1,0.3,1.4,2,1,1,1) datapredj_longi[3,] <- c(1,0.6,1.9,2,1,1,1)
datapredj_longi[4,] <- c(1,0.9,2.5,2,1,1,1) datapredj_longi[5,] <-
c(1,1.5,3.9,2,1,1,1)

# patient 2: decreasing tumor size datapredj_longi[6,] <- c(2, 0,1.2
,2,1,1,1) datapredj_longi[7,] <- c(2,0.3,0.7,2,1,1,1) datapredj_longi[8,] <-
c(2,0.5,0.3,2,1,1,1) datapredj_longi[9,] <- c(2,0.7,0.1,2,1,1,1)
datapredj_longi[10,] <- c(2,0.9,0.1,2,1,1,1)
```

Value

The following components are included in a 'predFrailty' object obtained by using prediction function for Cox proportional hazard and shared frailty model.

npred	Number of individual predictions
x.time	A vector of prediction times of interest (used for plotting predictions): vector of prediction times t if fixed window. Otherwise vector of prediction times t+w
window	Prediction window or vector of prediction windows
pred	Predictions estimated for each profile
icproba	Logical value. Were confidence intervals estimated ?
predLow	Lower limit of Monte-Carlo confidence interval for each prediction
predHigh	Upper limit of Monte-Carlo confidence interval for each prediction
type	Type of prediction probability (marginal or conditional)
group	For conditional probability, the list of group on which you make predictions

The following components are included in a 'predJoint' object obtained by using prediction function for joint frailty model.

npred	Number of individual predictions
x.time	A vector of prediction times of interest (used for plotting predictions): vector of prediction times t if fixed window. Otherwise vector of prediction times t+w
window	Prediction window or vector of prediction windows
group	Id of each patient
pred1	Estimation of probability of type 1: exactly j recurrences
pred2	Estimation of probability of type 2: at least j recurrences
pred3	Estimation of probability of type 3
pred1_rec	Estimation of prediction of relapse
icproba	Logical value. Were confidence intervals estimated ?
predlow1	Lower limit of Monte-Carlo confidence interval for probability of type 1
predhigh1	Upper limit of Monte-Carlo confidence interval for probability of type 1
predlow2	Lower limit of Monte-Carlo confidence interval for probability of type 2
predhigh2	Upper limit of Monte-Carlo confidence interval for probability of type 2
predlow3	Lower limit of Monte-Carlo confidence interval for probability of type 3
predhigh3	Upper limit of Monte-Carlo confidence interval for probability of type 3
predhigh1_rec	Upper limit of Monte-Carlo confidence interval for prediction of relapse
predlow1_rec	Lower limit of Monte-Carlo confidence interval for prediction of relapse

The following components are included in a 'predLongi' object obtained by using prediction function for joint models with longitudinal data.

npred	Number of individual predictions

x.time	A vector of prediction times of interest (used for plotting predictions): vector of prediction times t if fixed window. Otherwise vector of prediction times t+w
window	Prediction window or vector of prediction windows
group	Id of each patient
pred	Estimation of probability
icproba	Logical value. Were confidence intervals estimated?
predLow	Lower limit of Monte-Carlo confidence intervals
predHigh	Upper limit of Monte-Carlo confidence intervals
trivariate	Logical value. Are the prediction calculated from the trivariate model?

print.additivePenal   *Print a Short Summary of parameter estimates of an additive frailty*
                             model

Description

Prints a short summary of the parameter estimates of an additive frailty model or more generally of
an 'additivePenal' object

Usage

```
## S3 method for class 'additivePenal'
print(x, digits = max(options()$digits - 4, 6),
...)
```

Arguments

x	the result of a call to the additivePenal function
digits	number of digits to print
...	other unused arguments

Value

Print the parameter estimates of the survival or hazard functions.

See Also

[additivePenal](#)

---

print.Cmeasures   *Print a short summary of results of Cmeasure function.*

Description

Print a short summary of results of the concordance measure estimated by the Cmeasure function.

Usage

```
## S3 method for class 'Cmeasures'
print(x, ...)
```

Arguments

x	a Cmeasures object.
...	Other unused arguments

print.frailtyPenal   *Print a Short Summary of parameter estimates of a shared frailty model*

Description

Prints a short summary of parameter estimates of a 'frailtyPenal' object

Usage

```
## S3 method for class 'frailtyPenal'
print(x, digits = max(options()$digits - 4, 6),
...)
```

Arguments

x	the result of a call to the frailtyPenal function.
digits	number of digits to print.
...	other unused arguments.

Value

Print the parameter estimates of the survival or hazard functions.

See Also

[frailtyPenal](#)

---

print.jointNestedPenal

Print a Short Summary of parameter estimates of a joint nested frailty model

---

Description

Prints a short summary of parameter estimates of a joint nested frailty model, or more generally an object of class 'jointNestedPenal' for joint nested frailty models.

Usage

```
## S3 method for class 'jointNestedPenal'
print(x, digits = max(options()$digits - 4,
6), ...)
```

Arguments

x	the result of a call to the jointNestedPenal function
digits	number of digits to print
...	other unused arguments

Value

Print, separately for each type of event (recurrent and terminal), the parameter estimates of the survival or hazard functions.

See Also

[frailtyPenal](#)

---

print.jointPenal *Print a Short Summary of parameter estimates of a joint frailty model*

Description

Prints a short summary of parameter estimates of a joint frailty model, or more generally an object of class 'frailtyPenal' for joint frailty models.

Usage

```
## S3 method for class 'jointPenal'
print(x, digits = max(options()$digits - 4, 6), ...)
```

Arguments

x	the result of a call to the jointPenal function
digits	number of digits to print
...	other unused arguments

Value

Print, separately for each type of event (recurrent and terminal), the parameter estimates of the survival or hazard functions.

See Also

[frailtyPenal](#)

print.jointSurroPenal   *Summary of the random effects parameters, the fixed treatment effects, and the surrogacy evaluation criteria estimated from a joint surrogate model*

Description

This function returns the estimate of the coefficients and their standard error with p-values of the Wald test for the joint surrogate model, also hazard ratios (HR) and their confidence intervals for the fixed treatment effects, and finaly an estimate of the surrogacy evaluation criterian (Kendall's τ and R^2_{trial})

Usage

```
## S3 method for class 'jointSurroPenal'
print(x, d = 4, len = 3, nb.gh = 32, ...)
```

Arguments

x	An object inheriting from jointSurroPenal class.
d	The desired number of digits after the decimal point for parameters. The maximum of 4 digits is required for the estimates. Default of 3 digits is used.
len	The desired number of digits after the decimal point for p-value and convergence criteria. Default of 4 digits is used.
nb.gh	Number of nodes for the Gaussian-Hermite quadrature. The default is 32 1 for Gaussian-Hermite quadrature.
...	other unused arguments.

Value

For the variances parameters of the random effects, it prints the estimate of the coefficients with their standard error, Z-statistics and p-values of the Wald test. For the fixed treatment effects, it also prints HR and its confidence intervals for each covariate. For the surrogacy evaluation criteria, its prints the estimated Kendall's τ with its 95% Confidence interval obtained by the parametric bootstrap or Delta-method, the estimated R^2_{trial} (R2trial) with standard error and the 95% Confidence interval obtained by Delta-method (Dowd *et al.*, 2014), R^2_{trial} (R2.boot) and its 95% Confidence interval obtained by the parametric bootstrap. We notice that, using bootstrap, the standard error of the point estimate is not available. We propose a classification of R^2_{trial} according to the suggestion of the Institute of Quality and Efficiency in Health Care (Prasad *et al.*, 2015). We also display the surrogate threshold effect ([ste](ste)) with the associated hazard risk. The rest of parameters concerns the convergence characteristics and included: the penalized marginal log-likelihood, the number of iterations, the LCV and the Convergence criteria.

slope   *Identify variable associated with the random slope*

Description

This is a special function used in the context of survival additive models. It identifies the variable
which is in interaction with the random slope (v_i). Generally, this variable is the treatment variable.
Using interaction() in a formula implies that an additive frailty model is fitted.

Usage

```
slope(x)
```

Arguments

x   A factor, a character or a numerical variable

Value

x   The variable in interaction with the random slope

Note

It is necessary to specify which variable is in interaction with the random slope, even if only one explanatory variable is included in the model.

## End(Not run)
```

ste	*Surrogate threshold effect for the one-step Joint surrogate model for the evaluation of a canditate surrogate endpoint.*

Description

This function compute the surrogate threshold effect (STE) from the one-step joint frailty [model](#) or joint frailty-copula [model](#). The STE is defined as the minimum treament effect on surrogate endpoint, necessary to predict a non-zero effect on true endpoint (Burzykowski *et al.*, 2006).

Usage

```
ste(object, var.used = "error.estim", alpha. = 0.05,
    pred.int.use = "up")
```

Arguments

object	An object inheriting from `jointSurroPenal` class (output from calling the `jointSurroPenal` or `jointSurroCopPenal` function).
var.used	This argument takes two values. The first one is `"error.estim"` and indicates if the prediction error takes into account the estimation error of the estimates of the parameters. If the estimates are supposed to be known or if the dataset includes a high number of trials with a high number of subject per trial, value `No.error` can be used. The default is `error.estim`, which is highly recommended in practice.
alpha.	The confidence level for the prediction interval. The default is `0.05`
pred.int.use	A character string that indicates the bound of the prediction interval to use to compute the STE. Possible values are `up` for the upper bound (the default) or `lw` for the lower bound. `up` when we have a protective treatment effect and `lw` when we have a deleterious treatment effect (see details).

Details

The STE is obtained by solving the equation $l(\alpha_0)$ = 0 (resp. $u(\alpha_0)$ = 0), where α_0 represents the corresponding STE, and $l(\alpha_0)$ (resp. $u(\alpha_0)$) is the lower (resp. upper) bound of the prediction interval of the treatment effect on the true endpoint $(\beta + b_0)$. Thereby,

$$l(\alpha_0) \equiv E(\beta + b_0 | \alpha_0, \vartheta) - Z_{1-(\gamma/2)} \sqrt{(Var(\beta + b_0 | \alpha_0, \vartheta))}$$

and

$$u(\alpha_0) \equiv E(\beta + b_0 | \alpha_0, \vartheta) + Z_{1-(\gamma/2)} \sqrt{(Var(\beta + b_0 | \alpha_0, \vartheta))}$$

where ϑ represents the set of estimates for the fixed-effects and the variance-covariance parameters of the random effects obtained from the joint surrogate [model](#) (Sofeu *et al.*, 2019).

If the previous equations gives two solutions, STE can be the minimum (resp. the maximum) value or both of them, according to the shape of the function. If the concavity of the function is turned upwards, STE is the first value and the second value represents the maximum (res. the minimum) treament value observable on the surrogate that can predict a nonzero treatment effect

on true endpoint. If the concavity of the function is turned down, both of the solutions represent the STE and the interpretation is such that accepted values of the treatment effects on S predict a nonzero treatment effects on T

Given that negative values of treatment effect indicate a reduction of the risk of failure and are considered beneficial, STE is recommended to be computed from the upper prediction limit $u(\alpha_0)$.

The details on the computation of STE are described in Burzykowski *et al.* (2006).

Value

Returns and displays the STE.

subcluster	*Identify subclusters*

Description

This is a special function used in the context of survival nested or joint nested models. It identifies correlated groups of observations within other groups defined by using 'cluster' function from 'survival' package, and is used on the right hand side of 'frailtyPenal' formula for fitting a nested or joint nested model. Using subcluster() in a formula implies that a nested or a joint nested frailty model is estimated.

Usage

```
subcluster(x)
```

Arguments

x   A character, factor, or numeric variable which is supposed to indicate the variable subgroup

Value

x   A variable identified as a subcluster

summary.jointSurroMed *Short summary of the random effects parameters, the fixed treatment effects, and the surrogacy evaluation criteria estimated from a joint surrogate mediation model*

Description

This function returns the estimate of the coefficients of the model, their standard error and the associated p-values of the Wald test for the joint surrogate model, also hazard ratios (HR) and their confidence intervals for the fixed treatment effects. It also displays summary of the surrogacy measure $R(t)$ and of the natural direct, indirect and total effect.

Usage

```
## S3 method for class 'jointSurroMed'
summary(object,d=4,len=3,n=3,...)
```

Arguments

object	An object inheriting from jointSurroMed class.
d	The desired number of digits after the decimal point for parameters. The maximum of 4 digits is required for the estimates. Default of 3 digits is used.
len	The desired number of digits after the decimal point for p-value and convergence criteria. Default of 4 digits is used.
n	The number of time points to be used in the results of the differents function related to the mediation analysis: $g(s)$, $R(t)$ and the direct, indirect and total effect. The provided value should be between 1 and 20. Default is 3.
...	other unused arguments.

Value

For the variances parameters of the random effects, it prints the estimate of the coefficients with their standard error, Z-statistics and p-values of the Wald test. For the fixed treatment effects, it also prints HR and its confidence intervals for each covariate. For the surrogacy assessment, prints n value of the estimation function $g(s)$ and $R(t)$. Also prints the values of the estimated direct, indirect and total effects. The remaining displayed information concern the convergence characteristics and include the penalized marginal log-likelihood, the number of iterations, the LCV and the convergence criteria.

See Also

jointSurroPenal

summary.jointSurroPenal

Short summary of the surrogacy evaluation criteria estimated from a joint surrogate model

Description

This function returns the estimate of the coefficient, the hazard ratios (HR) and their confidence intervals for the fixed treatment effects. Also, an estimate of the surrogacy evaluation criteria (Kendall's τ, R^2_{trial} and STE)

Usage

```
## S3 method for class 'jointSurroPenal'
summary(object, d = 4, len = 3, nb.gh = 32, ...)
```

Arguments

object   An object inheriting from jointSurroPenal class.

d   The desired number of digits after the decimal point for parameters. The maximum of 4 digits is required for the estimates. Default of 3 digits is used.

len   The desired number of digits after the decimal point for p-value and convergence criteria. Default of 4 digits is used.

nb.gh   Number of nodes for the Gaussian-Hermite quadrature. The default is 32 1 for Gaussian-Hermite quadrature.

...   other unused arguments.

Value

For the fixed treatment effects, it also prints HR and its confidence intervals for each covariate. For the surrogacy evaluation criteria, its prints the estimated Kendall's τ with its 95% Confidence interval obtained by the parametric bootstrap or Delta-method, the estimated R^2_{trial} (R2trial) with standard error and the 95% Confidence interval obtained by Delta-method (Dowd *et al.*, 2014), R^2_{trial} (R2.boot) and its 95% Confidence interval obtained by the parametric bootstrap. We notice that, using bootstrap, the standard error of the point estimate is not available. We propose a classification of R^2_{trial} according to the suggestion of the Institute of Quality and Efficiency in Health Care (Prasad *et al.*, 2015). We also display the surrogate threshold effect ([ste](#)) with the associated hazard risk.

summary.jointSurroPenalSimul

Short summary of the simulation studies based on a joint surrogate model

---

Description

This function returns the true value, the mean of the estimates, the empirical standard error, the mean of the estimated standard errors (Mean SE), and the coverage probability for model parameters

Usage

```
## S3 method for class 'jointSurroPenalSimul'
summary(object, d = 3, R2boot = 0, displayMSE = 0, printResult = 1, CP = 0,  ...)
```

Arguments

`object`	an object inheriting from `jointSurroPenalSimul` class.
`d`	The desired number of digits after the decimal point f. Default of 3
`R2boot`	A binary that specifies whether the confidence interval of R^2_{trial} should be computed using parametric bootstrap (1) or Delta-method (0). The default is 0
`displayMSE`	A binary that indicates if the results include bias and mean square errors (MSE), case 1, or the standard errors with the coverage percentage, case 0. By default this argument is set to 0. In the event of 1 the results just include the individual level and the trial level association measurements.
`printResult`	A binary that indicates if the summary of the results should be displayed (1) or not (0). If this argument is set to 0, resuls are just returned to the user
`CP`	A binary that indicate in the event of `displayMSE = 1` if the percentage of coverage should be display (1) or not (0). The default is 0
`...`	other unused arguments.

Value

For each parameter of the joint surrogate model , we print the true simulation value, the empirical standard error (empirical SE), the mean of the estimated standard errors (Mean SE), and the coverate probability (CP). For Kendall's τ, the 95% Confidence interval is obtained by parametric bootstrap (for joint frailty model) or Delta-method (for joint frailty-copula model). For R^2_{trial} (R2trial), the standard error is obtained by Delta-method and the 95% Confidence interval could be obtained directly or by parametric bootstrap. We also display the total number of non convergence case with the associated percentage (R : n(%)), the mean number of iterations to reach convergence, and other estimation and simulation parameters. We also return a dataframe of the simulations results .

summary.longiPenal	*Short summary of fixed covariates estimates of a joint model for longitudinal data and a terminal event*

Description

This function returns coefficients estimates and their standard error with p-values of the Wald test for the longitudinal outcome and hazard ratios (HR) and their confidence intervals for the terminal event.

Usage

```
## S3 method for class 'longiPenal'
summary(object, level = 0.95, len = 6, d = 2,
lab=c("coef","hr"), ...)
```

Arguments

object	an object inheriting from longiPenal class
level	significance level of confidence interval. Default is 95%.
len	the total field width for the terminal part. Default is 6.
d	the desired number of digits after the decimal point. Default of 6 digits is used.
lab	labels of printed results for the longitudinal outcome and the terminal event respectively.
...	other unused arguments.

Value

For the longitudinal outcome it prints the estimates of coefficients of the fixed covariates with their standard error and p-values of the Wald test. For the terminal event it prints HR and its confidence intervals for each covariate. Confidence level is allowed (level argument).

survDat   *Survival dataset (TPJM)*

Description

This is a simulated dataset used to illustrate the two-part joint model included in the longiPenal function.

Usage

```
data(survDat)
```

Format

This data frame contains the following columns:

id The identification number of a patient

deathTimes The event times (death or censoring)

d Censoring indicator

trt Treatment covariate

SurvIC   *Create a survival object for interval censoring and possibly left truncated data*

Description

This is a function used in case of interval-censoring as a response variable in a model formula only for Cox proportional hazard or shared frailty model. Sometimes, an unobserved event might occur in a time interval [L,U]. RecurrentAG argument gets invalid with the use of SurvIC. Note that this function used a Kronecker product which can suffer from computation issue when the number of subjects in each cluster is high. Time dependent variables are not allowed.

Usage

```
SurvIC(t0, lower, upper, event)
```

Arguments

t0	Truncation time for left truncated data only. To be ignored otherwise.
lower	Starting time of the interval for interval-censored data. Time of right-censoring instead.
upper	Ending time of the interval for interval-censored data. For right-censored data, lower and upper time must be equal (for numerical reason).
event	Status indicator 0=right-censored, 1=interval-censored

Details

Typical usages are SurvIC(lower,upper,event) or SurvIC(t0,lower,upper,event)

Examples

```
## Not run:

data(bcos)
bcos$event <- ifelse(bcos$left!=bcos$right,1,0)

###---  Cox proportional hazard model with interval censoring ---###

cox.ic <- frailtyPenal(SurvIC(left,right,event)~treatment,
data=bcos,n.knots=8,kappa=10000)

###---  Shared model with interval censoring ---###

bcos$group <- c(rep(1:20,4),1:14)

sha.ic <- frailtyPenal(SurvIC(left,right,event)~cluster(group)+
treatment,data=bcos,n.knots=8,kappa=10000)

## End(Not run)
```

---

survival	*Survival function*

Description

Let t be a continuous variable, we determine the value of the survival function to t after run fit.

Usage

```
survival(t, ObjFrailty)
```

Arguments

t	time for survival function.
ObjFrailty	an object from the frailtypack fit.

Value

return the value of survival function in t.

Examples

```
## Not run:

#-- a fit Shared
data(readmission)

fit.shared <- frailtyPenal(Surv(time,event)~dukes+cluster(id)+
strata(sex),n.knots=10,kappa=c(10000,10000),data=readmission)

#-- calling survival
survival(20,fit.shared)

## End(Not run)
```

---

terminal   *Identify terminal indicator*

Description

This is a special function used in the context of recurrent event models with terminal event (e.g., censoring variable related to recurrent events). It contains the status indicator, normally 0=alive, 1=dead, and is used on the right hand side of a formula of a 'frailtyPenal', 'longiPenal' and 'trivPenal' functions. Using `terminal()` in a formula implies that a joint frailty model for recurrent events and terminal events is fitted.

Usage

```
terminal(x)
```

Arguments

x	A numeric variable but should be a Boolean which equals 1 if the subject is dead and 0 if he is alive or censored, as a death indicator.

Value

x   a death indicator

See Also

frailtyPenal

---

timedep   *Identify time-varying effects*

Description

This is a special function used in the context of Cox models and shared and joint frailty models. It identifies time-varying effects of covariates in the model. It is used in 'frailtyPenal' on the right hand side of formula or of formula.terminalEvent.

When considering time-varying effects in a survival model, regression coefficients can be modeled with a linear combination of B-splines $B(t)$ with coefficients ζ of order q with m interior knots :

$$\beta(t) = \sum_{j=-q+1}^{m} \zeta_j B_{j,q}(t)$$

You can notice that a linear combination of B-splines of order 1 without any interior knots (0 interior knot) is the same as a model without time-varying effect (or with constant effect over time).

Statistical tests (likelihood ratio tests) can be done in order to know whether the time-dependent coefficients are significantly different from zero or to test whether a covariate has a time-dependent effect significantly different from zero or not. These tests are correct only with a parametric approach yet.

- Proportional Hazard assumption ?

Time-dependency of a covariate effect can be tested. We need to estimate $m + q$ parameters ζ_j for $j = -q + 1, ..., m$ for a time-varying coefficient. Only one ($q = 1, m = 0$) parameter is estimated for a constant effect. A global test is done.

$$H_0 : \beta(t) = \beta$$

The corresponding LR statistic has a χ^2 distribution of degree $m + q - 1$.

- Significant association ?

We can also use a LR test to test whether a covariate has a significant effect on the hazard function. The null hypothesis is :

$$H_0 : \beta(t) = 0$$

For that we fit a model considering the covariate with a regression coefficent modeled using B-splines and a model without the covariate. Hence, the LR statistic has a χ^2 distribution of degree $m + q$.

Usage

```
timedep(x)
```

Arguments

x   A numerical or a factor variable that would have a time-varying effect on the event

Value

x   A variable identified with a time-varying effect

| trivPenal | *Fit a Trivariate Joint Model for Longitudinal Data, Recurrent Events and a Terminal Event* |

Description

Fit a trivariate joint model for longitudinal data, recurrent events and a terminal event using a semi-parametric penalized likelihood estimation or a parametric estimation on the hazard functions.

The longitudinal outcomes $y_i(t_{ik})$ $(k = 1, \ldots, n_i, i = 1, \ldots, N)$ for N subjects are described by a linear mixed model and the risks of the recurrent and terminal events are represented by proportional hazard risk models. The joint model is constructed assuming that the processes are linked via a latent structure (Krol et al. 2015):

$$
\left\{
\begin{array}{ll}
y_i(t_{ik}) = \boldsymbol{X}_{Li}(t_{ik})^\top \boldsymbol{\beta}_L + \boldsymbol{Z}_i(t_{ik})^\top \boldsymbol{b}_i + \epsilon_i(t_{ik}) & \text{(Longitudinal)} \\
r_{ij}(t|\boldsymbol{b}_i) = r_0(t) \exp(v_i + \boldsymbol{X}_{Rij}(t)\boldsymbol{\beta}_R + g(\boldsymbol{b}_i, \boldsymbol{\beta}_L, \boldsymbol{Z}_i(t), \boldsymbol{X}_{Li}(t))^\top \boldsymbol{\eta}_R) & \text{(Recurrent)} \\
\lambda_i(t|\boldsymbol{b}_i) = \lambda_0(t) \exp(\alpha v_i + \boldsymbol{X}_{Ti}(t)\boldsymbol{\beta}_T + h(\boldsymbol{b}_i, \boldsymbol{\beta}_L, \boldsymbol{Z}_i(t), \boldsymbol{X}_{Li}(t))^\top \boldsymbol{\eta}_T) & \text{(Terminal)}
\end{array}
\right.
$$

where $\boldsymbol{X}_{Li}(t)$, $\boldsymbol{X}_{Rij}(t)$ and $\boldsymbol{X}_{Ti}$ are vectors of fixed effects covariates and $\boldsymbol{\beta}_L$, $\boldsymbol{\beta}_R$ and $\boldsymbol{\beta}_T$ are the associated coefficients. Measurements errors $\epsilon_i(t_{ik})$ are iid normally distributed with mean 0 and variance σ_ϵ^2. The random effects $\boldsymbol{b}_i = (b_{0i}, \ldots, b_{qi})^\top \sim \mathcal{N}(0, \boldsymbol{B}_1)$ are associated to covariates $\boldsymbol{Z}_i(t)$ and independent from the measurement error. The relationship between the biomarker and recurrent events is explained via $g(\boldsymbol{b}_i, \boldsymbol{\beta}_L, \boldsymbol{Z}_i(t), \boldsymbol{X}_{Li}(t))$ with coefficients $\boldsymbol{\eta}_R$ and between the biomarker and terminal event is explained via $h(\boldsymbol{b}_i, \boldsymbol{\beta}_L, \boldsymbol{Z}_i(t), \boldsymbol{X}_{Li}(t))$ with coefficients $\boldsymbol{\eta}_T$. Two forms of the functions $g(\cdot)$ and $h(\cdot)$ are available: the random effects $\boldsymbol{b}_i$ and the current biomarker level $m_i(t) = \boldsymbol{X}_{Li}(t_{ik})^\top \boldsymbol{\beta}_L + \boldsymbol{Z}_i(t_{ik})^\top \boldsymbol{b}_i$. The frailty term v_i is gaussian with mean 0 and variance σ_v. Together with $\boldsymbol{b}_i$ constitutes the random effects of the model:

$$
\boldsymbol{u}_i = \left(\begin{array}{c} \mathbf{b}_i \\ v_i \end{array} \right) \sim \mathcal{N} \left(\mathbf{0}, \left(\begin{array}{cc} \mathbf{B}_1 & \mathbf{0} \\ \mathbf{0} & \sigma_v^2 \end{array} \right) \right),
$$

We consider that the longitudinal outcome can be a subject to a quantification limit, i.e. some observations, below a level of detection s cannot be quantified (left-censoring).

Usage

```
trivPenal(formula, formula.terminalEvent, formula.LongitudinalData, data,
data.Longi, random, id, intercept = TRUE, link = "Random-effects",
left.censoring = FALSE, recurrentAG = FALSE, n.knots, kappa, maxit = 300,
hazard = "Splines", init.B, init.Random, init.Eta, init.Alpha, method.GH =
"Standard", n.nodes, LIMparam = 1e-3, LIMlogl = 1e-3, LIMderiv = 1e-3,
print.times = TRUE)
```

Arguments

formula   a formula object, with the response on the left of a $\sim$ operator, and the terms on the right. The response must be a survival object as returned by the 'Surv' function like in survival package. Interactions are possible using * or :.

formula.terminalEvent

A formula object, only requires terms on the right to indicate which variables are modelling the terminal event. Interactions are possible using * or :.

formula.LongitudinalData

A formula object, only requires terms on the right to indicate which variables are modelling the longitudinal outcome. It must follow the standard form used for linear mixed-effects models. Interactions are possible using * or :.

data   A 'data.frame' with the variables used in `formula`.

data.Longi   A 'data.frame' with the variables used in `formula.LongitudinalData`.

random   Names of variables for the random effects of the longitudinal outcome. Maximum 3 random effects are possible at the moment. The random intercept is chosen using "1".

id   Name of the variable representing the individuals.

intercept   Logical value. Is the fixed intercept of the biomarker included in the mixed-effects model? The default is `TRUE`.

link   Type of link functions for the dependence between the biomarker and death and between the biomarker and the recurrent events: "Random-effects" for the association directly via the random effects of the biomarker, "Current-level" for the association via the true current level of the biomarker. The option "Current-level" can be chosen only if the biomarker random effects are associated with the intercept and time (following this order). The default is "Random-effects".

left.censoring Is the biomarker left-censored below a threshold s? If there is no left-censoring, the argument must be equal to `FALSE`, otherwise the value of the threshold must be given.

recurrentAG   Logical value. Is Andersen-Gill model fitted? If so indicates that recurrent event times with the counting process approach of Andersen and Gill is used. This formulation can be used for dealing with time-dependent covariates. The default is FALSE.

n.knots   Integer giving the number of knots to use. Value required in the penalized likelihood estimation. It corresponds to the (n.knots+2) splines functions for the approximation of the hazard or the survival functions. We estimate I or M-splines of order 4. When the user set a number of knots equals to k (n.knots=k) then the number of interior knots is (k-2) and the number of splines is (k-2)+order. Number of knots must be between 4 and 20. (See Note in `frailtyPenal` function)

kappa   Positive smoothing parameters in the penalized likelihood estimation. The coefficient kappa of the integral of the squared second derivative of hazard function in the fit (penalized log likelihood). To obtain an initial value for `kappa`, a solution is to fit the corresponding Cox model using cross validation (See `cross.validation` in function `frailtyPenal`). We advise the user to identify several possible tuning parameters, note their defaults and look at the sensitivity of the results to varying them.

maxit   Maximum number of iterations for the Marquardt algorithm. Default is 300

hazard   Type of hazard functions: "Splines" for semiparametric hazard functions using equidistant intervals or "Splines-per" using percentile with the penalized likelihood estimation, "Weibull" for the parametric Weibull functions. The default is "Splines".

init.B	Vector of initial values for regression coefficients. This vector should be of the same size as the whole vector of covariates with the first elements for the covariates related to the recurrent events, then to the terminal event and then to the biomarker (interactions in the end of each component). Default is 0.5 for each.
init.Random	Initial value for variance of the elements of the matrix of the distribution of the random effects.
init.Eta	Initial values for regression coefficients for the link functions, first for the recurrent events ($\boldsymbol{\eta}_R$) and for the terminal event ($\boldsymbol{\eta}_T$).
init.Alpha	Initial value for parameter alpha
method.GH	Method for the Gauss-Hermite quadrature: "Standard" for the standard non-adaptive Gaussian quadrature, "Pseudo-adaptive" for the pseudo-adaptive Gaussian quadrature and "HRMSYM" for the algorithm for the multivariate non-adaptive Gaussian quadrature (see Details). The default is "Standard".
n.nodes	Number of nodes for the Gauss-Hermite quadrature. They can be chosen amon 5, 7, 9, 12, 15, 20 and 32. The default is 9.
LIMparam	Convergence threshold of the Marquardt algorithm for the parameters (see Details), 10^{-3} by default.
LIMlogl	Convergence threshold of the Marquardt algorithm for the log-likelihood (see Details), 10^{-3} by default.
LIMderiv	Convergence threshold of the Marquardt algorithm for the gradient (see Details), 10^{-3} by default.
print.times	a logical parameter to print iteration process. Default is TRUE.

Details

Typical usage for the joint model

```
trivPenal(Surv(time,event)~cluster(id) + var1 + var2 +
terminal(death), formula.terminalEvent =~ var1 + var3, biomarker ~
var1+var2, data, data.Longi, ...)
```

The method of the Gauss-Hermite quadrature for approximations of the multidimensional integrals, i.e. length of random is 2, can be chosen among the standard, non-adaptive, pseudo-adaptive in which the quadrature points are transformed using the information from the fitted mixed-effects model for the biomarker (Rizopoulos 2012) or multivariate non-adaptive procedure proposed by Genz et al. 1996 and implemented in FORTRAN subroutine HRMSYM. The choice of the method is important for estimations. The standard non-adaptive Gauss-Hermite quadrature ("Standard") with a specific number of points gives accurate results but can be time consuming. The non-adaptive procedure ("HRMSYM") offers advantageous computational time but in case of datasets in which some individuals have few repeated observations (biomarker measures or recurrent events), this method may be moderately unstable. The pseudo-adaptive quadrature uses transformed quadrature points to center and scale the integrand by utilizing estimates of the random effects from an appropriate linear mixed-effects model (this transformation does not include the frailty in the trivariate model, for which the standard method is used). This method enables using less quadrature points while preserving the estimation accuracy and thus lead to a better computational time.

NOTE. Data frames data and data.Longi must be consistent. Names and types of corresponding covariates must be the same, as well as the number and identification of individuals.

Value

The following components are included in a 'trivPenal' object for each model:

b	The sequence of the corresponding estimation of the coefficients for the hazard functions (parametric or semiparametric), the random effects variances and the regression coefficients.
call	The code used for the model.
formula	The formula part of the code used for the recurrent event part of the model.
formula.terminalEvent	
	The formula part of the code used for the terminal event part of the model.
formula.LongitudinalData	
	The formula part of the code used for the longitudinal part of the model.
coef	The regression coefficients (first for the recurrent events, then for the terminal event and then for the biomarker.
groups	The number of groups used in the fit.
kappa	The values of the smoothing parameters in the penalized likelihood estimation corresponding to the baseline hazard functions for the recurrent and terminal events.
logLikPenal	The complete marginal penalized log-likelihood in the semiparametric case.
logLik	The marginal log-likelihood in the parametric case.
n.measurements	The number of biomarker observations used in the fit.
max_rep	The maximal number of repeated measurements per individual.
n	The number of observations in 'data' (recurrent and terminal events) used in the fit.
n.events	The number of recurrent events observed in the fit.
n.deaths	The number of terminal events observed in the fit.
n.iter	The number of iterations needed to converge.
n.knots	The number of knots for estimating the baseline hazard function in the penalized likelihood estimation.
n.strat	The number of stratum.
varH	The variance matrix of all parameters (before positivity constraint transformation for the variance of the measurement error, for which the delta method is used).
varHIH	The robust estimation of the variance matrix of all parameters.
xR	The vector of times where both survival and hazard function of the recurrent events are estimated. By default seq(0,max(time),length=99), where time is the vector of survival times.
lamR	The array (dim=3) of baseline hazard estimates and confidence bands (recurrent events).
survR	The array (dim=3) of baseline survival estimates and confidence bands (recurrent events).

xD	The vector of times where both survival and hazard function of the terminal event are estimated. By default seq(0,max(time),length=99), where time is the vector of survival times.
lamD	The array (dim=3) of baseline hazard estimates and confidence bands.
survD	The array (dim=3) of baseline survival estimates and confidence bands.
medianR	The value of the median survival and its confidence bands for the recurrent event.
medianD	The value of the median survival and its confidence bands for the terminal event.
typeof	The type of the baseline hazard function (0:"Splines", "2:Weibull").
npar	The number of parameters.
nvar	The vector of number of explanatory variables for the recurrent events, terminal event and biomarker.
nvarRec	The number of explanatory variables for the recurrent events.
nvarEnd	The number of explanatory variables for the terminal event.
nvarY	The number of explanatory variables for the biomarker.
noVarRec	The indicator of absence of the explanatory variables for the recurrent events.
noVarEnd	The indicator of absence of the explanatory variables for the terminal event.
noVarY	The indicator of absence of the explanatory variables for the biomarker.
LCV	The approximated likelihood cross-validation criterion in the semiparametric case (with H minus the converged Hessian matrix, and l(.) the full log-likelihood).

$$LCV = \frac{1}{n}(trace(H_{pl}^{-1}H) - l(.))$$

AIC	The Akaike information Criterion for the parametric case.

$$AIC = \frac{1}{n}(np - l(.))$$

n.knots.temp	The initial value for the number of knots.
shape.weib	The shape parameter for the Weibull hazard functions (the first element for the recurrences and the second one for the terminal event).
scale.weib	The scale parameter for the Weibull hazard functions (the first element for the recurrences and the second one for the terminal event).
martingale.res	The martingale residuals related to the recurrences for each individual.
martingaledeath.res	
	The martingale residuals related to the terminal event for each individual.
conditional.res	
	The conditional residuals for the biomarker (subject-specific): $\boldsymbol{R}_i^{(m)} = \boldsymbol{y}_i - \boldsymbol{X}_{Li}^\top \widehat{\boldsymbol{\beta}}_L - \boldsymbol{Z}_i^\top \widehat{\boldsymbol{b}}_i$.
marginal.res	The marginal residuals for the biomarker (population averaged): $\boldsymbol{R}_i^{(c)} = \boldsymbol{y}_i - \boldsymbol{X}_{Li}^\top \widehat{\boldsymbol{\beta}}_L$.

marginal_chol.res

The Cholesky marginal residuals for the biomarker: $\boldsymbol{R}_i^{(m)} = \widehat{\boldsymbol{U}_i^{(m)}} \boldsymbol{R}_i^{(m)}$, where $\widehat{\boldsymbol{U}_i^{(m)}}$ is an upper-triangular matrix obtained by the Cholesky decomposition of the variance matrix $\boldsymbol{V}_{\boldsymbol{R}_i^{(m)}} = \widehat{\boldsymbol{V}}_i - \boldsymbol{X}_{Li}(\sum_{i=1}^N \boldsymbol{X}_{Li}\widehat{\boldsymbol{V}}_i^{-1}\boldsymbol{X}_{Li})^{-1}\boldsymbol{X}_{Li}^\top$.

conditional_st.res

The standardized conditional residuals for the biomarker.

marginal_st.res

The standardized marginal residuals for the biomarker.

random.effects.pred

The empirical Bayes predictions of the random effects (ie. using conditional posterior distributions).

frailty.pred   The empirical Bayes predictions of the frailty term (ie. using conditional posterior distributions).

pred.y.marg   The marginal predictions of the longitudinal outcome.

pred.y.cond   The conditional (given the random effects) predictions of the longitudinal outcome.

linear.pred   The linear predictor for the recurrent events part.

lineardeath.pred

The linear predictor for the terminal event part.

global_chisqR   The vector with values of each multivariate Wald test for the recurrent part.

dof_chisqR   The vector with degrees of freedom for each multivariate Wald test for the recurrent part.

global_chisq.testR

The binary variable equals to 0 when no multivariate Wald is given, 1 otherwise (for the recurrent part).

p.global_chisqR

The vector with the p_values for each global multivariate Wald test for the recurrent part.

global_chisqT   The vector with values of each multivariate Wald test for the terminal part.

dof_chisqT   The vector with degrees of freedom for each multivariate Wald test for the terminal part.

global_chisq.testT

The binary variable equals to 0 when no multivariate Wald is given, 1 otherwise (for the terminal part).

p.global_chisqT

The vector with the p_values for each global multivariate Wald test for the terminal part.

global_chisqY   The vector with values of each multivariate Wald test for the longitudinal part.

dof_chisqY   The vector with degrees of freedom for each multivariate Wald test for the longitudinal part.

global_chisq.testY

The binary variable equals to 0 when no multivariate Wald is given, 1 otherwise (for the longitudinal part).

p.global_chisqY

        The vector with the p_values for each global multivariate Wald test for the longitudinal part.

names.factorR   The names of the "as.factor" variables for the recurrent part.

names.factorT   The names of the "as.factor" variables for the terminal part.

names.factorY   The names of the "as.factor" variables for the longitudinal part.

AG   The logical value. Is Andersen-Gill model fitted?

intercept   The logical value. Is the fixed intercept included in the linear mixed-effects model?

B1   The variance matrix of the random effects for the longitudinal outcome.

sigma2   The variance of the frailty term (σ_v).

alpha   The coefficient α associated with the frailty parameter in the terminal hazard function.

ResidualSE   The variance of the measurement error.

etaR   The regression coefficients for the link function $g(\cdot)$.

etaT   The regression coefficients for the link function $h(\cdot)$.

ne_re   The number of random effects b used in the fit.

names.re   The names of variables for the random effects $\boldsymbol{b}_i$.

link   The name of the type of the link functions.

leftCensoring   The logical value. Is the longitudinal outcome left-censored?

leftCensoring.threshold

        For the left-censored biomarker, the value of the left-censoring threshold used for the fit.

prop.censored   The fraction of observations subjected to the left-censoring.

methodGH   The Gaussian quadrature method used in the fit.

n.nodes   The number of nodes used for the Gaussian quadrature in the fit.

alpha_p.value   p-value of the Wald test for the estimated coefficient α.

sigma2_p.value p-value of the Wald test for the estimated variance of the frailty term (σ_v).

etaR_p.value   p-values of the Wald test for the estimated regression coefficients for the link function $g(\cdot)$.

etaT_p.value   p-values of the Wald test for the estimated regression coefficients for the link function $h(\cdot)$.

beta_p.value   p-values of the Wald test for the estimated regression coefficients.

Note

It is recommended to initialize the parameter values using the results from the reduced models (for example, longiPenal for the longitudinal and terminal part and frailtyPenal for the recurrent part. See example.

trivPenalNL	*Fit a Non-Linear Trivariate Joint Model for Recurrent Events and a Terminal Event with a Biomarker Described with an ODE Population Model*

Description

Fit a non-linear trivariate joint model for a longitudinal biomarker, recurrent events and a terminal event using a semiparametric penalized likelihood estimation or a parametric estimation on the hazard functions.

The values $y_i(t)$ $(i = 1, \ldots, N)$ for N subjects represent the individual evolution of the biomarker e.g. tumor size expressed as the sum of the longest diameters (SLD) of target lesions. The dynamics of the biomarker are described by an ordinary differential equation (ODE) that includes the effect of the natural net growth and the treatment effect:

$$\begin{cases} \frac{dy_i(t)}{dt} & = \exp(K_{G,0} + b_{G,i} + \boldsymbol{X}_{G,i}(t)^\top \boldsymbol{\beta}_G) y_i(t) \\ & \quad -d_i \exp(K_{D,0} + b_{D,i} - t \times \exp(\lambda + b_{\lambda,i}) + \boldsymbol{X}_{D,i}(t)^\top \boldsymbol{\beta}_D) y_i(t) \\ y_i(0) & = \exp(y_0 + b_{y_0,i}) \end{cases},$$

The model includes the following parameters (using the interpretation of tumor dynamics): $\exp(K_{G,0})$ the constant tumor growth rate, $\exp(K_{D,0})$ the drug-induced tumor decline rate, λ resistance effect to drug (exponential tumor decay change with time), $\exp(y_0)$ the initial level of the biomarker and d_i is the treatment concentration (e.g dose). The random effects $\boldsymbol{b}_i^\top = (b_{y_0,i}, b_{G,i}, b_{D,i}, b_{\lambda,i})^\top$ are gaussian variables with a diagonal covariance matrix $\boldsymbol{B}_1$. In the trivariate model we use the analytical solution of the equation with the population-based approach of the non-linear mixed effects model. We can also assume a transformation for the observations of the biomarker (one parameter Box-Cox transformation) and we include a gaussian measurement error, for individual i and observation k ($k = 1, \ldots, n_i$), $\epsilon_{ik} \sim N(0, \sigma_\epsilon^2)$.

The risks of the recurrent ($r_{ij}(\cdot)$ the risk of the j-th event of the individual i) and terminal events (λ_i the risk of the event of the individual i) are represented by proportional hazard risk models. The joint model is constructed assuming that the processes are linked via a latent structure and includes the non-linear mixed effects model for the longitudinal data:

$$\begin{cases} y(t_{ik}) & = \exp[y_0 + b_{y_0,i} + t_{ik} \times \exp(K_{G,0} + b_{G,i} + \boldsymbol{X}_{G,i}(t)^\top \boldsymbol{\beta}_G) \\ & \quad + d_i \times \exp(K_{D,0} + b_{D,i} - \lambda - b_{\lambda,i} + \boldsymbol{X}_{D,i}(t)^\top \boldsymbol{\beta}_D) \\ & \quad \times (\exp(-\exp(\lambda + b_{\lambda,i}) t_{ik}) - 1)] + \epsilon_{ik} \\ r_{ij}(t|\boldsymbol{b}_i) & = r_0(t) \exp(v_i + \boldsymbol{X}_{Rij}(t)^\top \boldsymbol{\beta}_R + g(y_i(t))^\top \boldsymbol{\eta}_R) \\ \lambda_i(t|\boldsymbol{b}_i) & = \lambda_0(t) \exp(\alpha v_i + \boldsymbol{X}_{Ti}(t)^\top \boldsymbol{\beta}_T + h(y_i(t))^\top \boldsymbol{\eta}_T) \end{cases}$$

where $\boldsymbol{X}_{G,i}(t)$, $\boldsymbol{X}_{D,i}(t)$, $\boldsymbol{X}_{R,ij}(t)$ and $\boldsymbol{X}_{T,i}(t)$ are vectors of possible time-varying fixed effects covariates and $\boldsymbol{\beta}_G$, $\boldsymbol{\beta}_D$, $\boldsymbol{\beta}_R$ and $\boldsymbol{\beta}_T$ are the associated coefficients. The random effects $\boldsymbol{b}_i$ are independent from the measurement error. The relationship between the biomarker and recurrent events is explained via $g(y_i(t))$ with coefficients $\boldsymbol{\eta}_R$ and between the biomarker and terminal event is explained via $h(y_i(t))$ with coefficients $\boldsymbol{\eta}_T$. Currently, only one form of the functions $g(\cdot)$ and $h(\cdot)$ is available: the random effects $\boldsymbol{b}_i$. The frailty term v_i is gaussian with mean 0 and variance σ_v. Together with $\boldsymbol{b}_i$ constitutes the random effects of the model:

$$\boldsymbol{u}_i = \begin{pmatrix} \mathbf{b}_i \\ v_i \end{pmatrix} \sim \mathcal{N} \left(\mathbf{0}, \begin{pmatrix} \mathbf{B}_1 & \mathbf{0} \\ \mathbf{0} & \sigma_v^2 \end{pmatrix} \right),$$

Any combination of the random effects $\boldsymbol{b}_i$, e.g. $\boldsymbol{b}_i = b_{y_0,i}$ or $\boldsymbol{b}_i = \{b_{G,i}, b_{D,i}, b_{\lambda,i}\}$ can be chosen for the model.

We consider that the longitudinal outcome can be a subject to a quantification limit, i.e. some observations, below a level of detection s cannot be quantified (left-censoring).

Usage

```
trivPenalNL(formula, formula.terminalEvent, biomarker, formula.KG,
formula.KD, dose, time.biomarker, data, data.Longi, random, id, link =
"Random-effects", BoxCox = FALSE, left.censoring = FALSE, recurrentAG =
FALSE, n.knots, kappa, maxit = 300, hazard = "Splines", init.B, init.Random,
init.Eta, init.Alpha, init.Biomarker, method.GH = "Standard", init.GH =
FALSE, n.nodes, LIMparam = 1e-3, LIMlogl = 1e-3, LIMderiv = 1e-3,
print.times = TRUE)
```

Arguments

formula	a formula object, with the response on the left of a $\sim$ operator, and the terms on the right. The response must be a survival object as returned by the 'Surv' function like in survival package. Interactions are possible using * or :.
formula.terminalEvent	
	A formula object, only requires terms on the right to indicate which variables are modelling the terminal event. Interactions are possible using * or :.
biomarker	Name of the variable representing the longitudinal biomarker.
formula.KG	A formula object, only requires terms on the right to indicate which covariates related to the biomarker growth are included in the longitudinal sub-model. It must follow the standard form used for linear mixed-effects models. Interactions are possible using * or :.
formula.KD	A formula object, only requires terms on the right to indicate which covariates related to the biomarker drug-induced decline are included in the longitudinal sub-model. It must follow the standard form used for linear mixed-effects models. Interactions are possible using * or :.
dose	Name of the variable representing the drug concentration indicator.
time.biomarker	Name of the variable of times of biomarker measurements.
data	A 'data.frame' with the variables used in formula.
data.Longi	A 'data.frame' with the variables used in formula.KG, formula.KD, biomarker, dose, time.biomarker and id.
random	Names of parameters for which the random effects are included in the mixed model. The names must be chosen among "y0", "KG", "KD" and "lambda". Any combination of the mentioned names is allowed.
id	Name of the variable representing the individuals.
link	Type of link functions for the dependence between the biomarker and death and between the biomarker and the recurrent events: only "Random-effects" for the association directly via the random effects of the biomarker is allowed for the moment (option for a future extension).
BoxCox	Should the Box-Cox transformation be used for the longitudinal biomarker? If there is no transformation, the argument must be equal to FALSE, otherwise the of the transformation parameter must be given, then the transformed values are $y^* = (y^\xi - 1)/\xi$, where ξ is the Box-Cox parameter.
left.censoring	Is the biomarker left-censored below a threshold s? If there is no left-censoring, the argument must be equal to FALSE, otherwise the value of the threshold must be given.
recurrentAG	Logical value. Is Andersen-Gill model fitted? If so indicates that recurrent event times with the counting process approach of Andersen and Gill is used. This formulation can be used for dealing with time-dependent covariates. The default is FALSE.
n.knots	Integer giving the number of knots to use. Value required in the penalized likelihood estimation. It corresponds to the (n.knots+2) splines functions for the approximation of the hazard or the survival functions. We estimate I or M-splines

	of order 4. When the user set a number of knots equals to k (n.knots=k) then the number of interior knots is (k-2) and the number of splines is (k-2)+order. Number of knots must be between 4 and 20. (See Note in `frailtyPenal` function)
kappa	Positive smoothing parameters in the penalized likelihood estimation. The coefficient kappa of the integral of the squared second derivative of hazard function in the fit (penalized log likelihood). To obtain an initial value for `kappa`, a solution is to fit the corresponding Cox model using cross validation (See `cross.validation` in function `frailtyPenal`). We advise the user to identify several possible tuning parameters, note their defaults and look at the sensitivity of the results to varying them.
maxit	Maximum number of iterations for the Marquardt algorithm. Default is 300
hazard	Type of hazard functions: `"Splines"` for semiparametric hazard functions using equidistant intervals or `"Splines-per"` using percentile with the penalized likelihood estimation, `"Weibull"` for the parametric Weibull functions. The default is `"Splines"`.
init.B	Vector of initial values for regression coefficients. This vector should be of the same size as the whole vector of covariates with the first elements for the covariates related to the recurrent events, then to the terminal event and then to the biomarker (interactions in the end of each component). Default is 0.5 for each.
init.Random	Initial value for variance of the elements of the matrix of the distribution of the random effects.
init.Eta	Initial values for regression coefficients for the link functions, first for the recurrent events ($\boldsymbol{\eta}_R$) and for the terminal event ($\boldsymbol{\eta}_T$).
init.Alpha	Initial value for parameter alpha
init.Biomarker	Initial values for biomarker parameters: y_0, $K_{G,0}$, $K_{D,0}$ and λ (using this order).
method.GH	Method for the Gauss-Hermite quadrature: `"Standard"` for the standard non-adaptive Gaussian quadrature and `"Pseudo-adaptive"` for the pseudo-adaptive Gaussian quadrature (see Details). The default is `"Standard"`. When the option `"Pseudo-adaptive"` is chosen, then a univariate model (non-linear mixed model for the biomarker) is fitted in order to obtain the estimations of the random effects $\boldsymbol{b}_i$.
init.GH	Only when the opiton `"Pseudo-adaptive"` of the argument `method.GH` is chosen. If TRUE, the estimations of the biomarker parameters (y_0, $K_{G,0}$, $K_{D,0}$ and λ), σ_ϵ, $\boldsymbol{\beta}_G$ and $\boldsymbol{\beta}_D$ from the univariate mixed model are used as the initial values of the parameters related to the biomarker.
n.nodes	Number of nodes for the Gauss-Hermite quadrature (from 5 to 32). The default is 9.
LIMparam	Convergence threshold of the Marquardt algorithm for the parameters (see Details), 10^{-3} by default.
LIMlogl	Convergence threshold of the Marquardt algorithm for the log-likelihood (see Details), 10^{-3} by default.
LIMderiv	Convergence threshold of the Marquardt algorithm for the gradient (see Details), 10^{-3} by default.
print.times	a logical parameter to print iteration process. Default is TRUE.

Details

Typical usage for the joint model

```
trivPenalNL(Surv(time,event)~cluster(id) + var1 + var2 +
terminal(death), formula.terminalEvent =~ var1 + var3, biomarker =
"biomarker.name", dose = "dose.name", time.biomarker = "time", formula.KG ~
var1, formula.KD ~ var2, data, data.Longi, ...)
```

The method of the Gauss-Hermite quadrature for approximations of the multidimensional integrals, i.e. length of random more than 2, can be chosen among the standard (non-adaptive) and pseudo-adaptive in which the quadrature points are transformed using the information from the fitted mixed-effects model for the biomarker (Rizopoulos 2012) or multivariate non-adaptive procedure proposed by Genz et al. 1996 and implemented in FORTRAN subroutine HRMSYM. The choice of the method is important for estimations. The standard non-adaptive Gauss-Hermite quadrature ("Standard") with a specific number of points gives accurate results but can be time consuming. The pseudo-adaptive quadrature uses transformed quadrature points to center and scale the integrand by utilizing estimates of the random effects from an appropriate non-linear mixed-effects model (this transformation does not include the frailty in the trivariate model, for which the standard method, with 20 quadrature points, is used). This method enables using less quadrature points while preserving the estimation accuracy and thus lead to a better computational time.

NOTE. Data frames data and data.Longi must be consistent. Names and types of corresponding covariates must be the same, as well as the number and identification of individuals.

Value

The following components are included in a 'trivPenalNL' object for each model:

b	The sequence of the corresponding estimation of the coefficients for the hazard functions (parametric or semiparametric), the random effects variances and the regression coefficients.
call	The code used for the model.
formula	The formula part of the code used for the recurrent event part of the model.
formula.terminalEvent	
	The formula part of the code used for the terminal event part of the model.
formula.KG	The formula part of the code used for the longitudinal part of the model, for the biomarker growth dynamics.
formula.KD	The formula part of the code used for the longitudinal part of the model, for the biomarker decline dynamics.
coef	The regression coefficients (first for the recurrent events, then for the terminal event, then for the biomarker growth and then for the biomarker decline.
groups	The number of groups used in the fit.
kappa	The values of the smoothing parameters in the penalized likelihood estimation corresponding to the baseline hazard functions for the recurrent and terminal events.
logLikPenal	The complete marginal penalized log-likelihood in the semiparametric case.

logLik	The marginal log-likelihood in the parametric case.
n.measurements	The number of biomarker observations used in the fit.
max_rep	The maximal number of repeated measurements per individual.
n	The number of observations in 'data' (recurrent and terminal events) used in the fit.
n.events	The number of recurrent events observed in the fit.
n.deaths	The number of terminal events observed in the fit.
n.iter	The number of iterations needed to converge.
n.knots	The number of knots for estimating the baseline hazard function in the penalized likelihood estimation.
n.strat	The number of stratum.
varH	The variance matrix of all parameters (before positivity constraint transformation for the variance of the measurement error, for which the delta method is used).
varHIH	The robust estimation of the variance matrix of all parameters.
xR	The vector of times where both survival and hazard function of the recurrent events are estimated. By default seq(0,max(time),length=99), where time is the vector of survival times.
lamR	The array (dim=3) of baseline hazard estimates and confidence bands (recurrent events).
survR	The array (dim=3) of baseline survival estimates and confidence bands (recurrent events).
xD	The vector of times where both survival and hazard function of the terminal event are estimated. By default seq(0,max(time),length=99), where time is the vector of survival times.
lamD	The array (dim=3) of baseline hazard estimates and confidence bands.
survD	The array (dim=3) of baseline survival estimates and confidence bands.
medianR	The value of the median survival and its confidence bands for the recurrent event.
medianD	The value of the median survival and its confidence bands for the terminal event.
typeof	The type of the baseline hazard function (0:"Splines", "2:Weibull").
npar	The number of parameters.
nvar	The vector of number of explanatory variables for the recurrent events, terminal event, biomarker growth and biomarker decline.
nvarRec	The number of explanatory variables for the recurrent events.
nvarEnd	The number of explanatory variables for the terminal event.
nvarKG	The number of explanatory variables for the biomarker growth.
nvarKD	The number of explanatory variables for the biomarker decline.
noVarRec	The indicator of absence of the explanatory variables for the recurrent events.
noVarEnd	The indicator of absence of the explanatory variables for the terminal event.
noVarKG	The indicator of absence of the explanatory variables for the biomarker growth.

noVarKD	The indicator of absence of the explanatory variables for the biomarker decline.
LCV	The approximated likelihood cross-validation criterion in the semiparametric case (with H minus the converged Hessian matrix, and l(.) the full log-likelihood).

$$LCV = \frac{1}{n}(trace(H_{pl}^{-1}H) - l(.))$$

AIC	The Akaike information Criterion for the parametric case.

$$AIC = \frac{1}{n}(np - l(.))$$

n.knots.temp	The initial value for the number of knots.
shape.weib	The shape parameter for the Weibull hazard functions (the first element for the recurrences and the second one for the terminal event).
scale.weib	The scale parameter for the Weibull hazard functions (the first element for the recurrences and the second one for the terminal event).
random.effects.pred	
	The empirical Bayes predictions of the random effects (ie. using conditional posterior distributions).
global_chisq.testR	
	The binary variable equals to 0 when no multivariate Wald is given, 1 otherwise (for the recurrent part).
global_chisq.testT	
	The binary variable equals to 0 when no multivariate Wald is given, 1 otherwise (for the terminal part).
global_chisq.testKG	
	The binary variable equals to 0 when no multivariate Wald is given, 1 otherwise (for the biomarker growth).
global_chisq.testKD	
	The binary variable equals to 0 when no multivariate Wald is given, 1 otherwise (for the biomarker decline).
AG	The logical value. Is Andersen-Gill model fitted?
B1	The variance matrix of the random effects for the longitudinal outcome.
sigma2	The variance of the frailty term (σ_v).
alpha	The coefficient α associated with the frailty parameter in the terminal hazard function.
ResidualSE	The variance of the measurement error.
etaR	The regression coefficients for the link function $g(\cdot)$.
etaT	The regression coefficients for the link function $h(\cdot)$.
ne_re	The number of random effects b used in the fit.
names.re	The names of variables for the random effects $\boldsymbol{b}_i$.
link	The name of the type of the link functions.
leftCensoring	The logical value. Is the longitudinal outcome left-censored?

leftCensoring.threshold

    For the left-censored biomarker, the value of the left-censoring threshold used for the fit.

prop.censored	The fraction of observations subjected to the left-censoring.
methodGH	The Gaussian quadrature method used in the fit.
n.nodes	The number of nodes used for the Gaussian quadrature in the fit.
K_G0	Value of the estimate of the biomarker growth parameter.
K_D0	Value of the estimate of the biomarker decay parameter.
lambda	Value of the estimate of the biomarker resistance to drug.
y_0	Value of the estimate of the biomarker intial level.
biomarker	Name of the variable associated with the biomarker in the data.
time.biomarker	Name of the variable associated with the time of measurements of the biomarker in the data.
dose	Name of the variable associated with the drug concentration in the data.
BoxCox	The logical value. Is the BoxCox transformation applied for the biomarker?

BoxCox_parameter

    The value of the BoxCox transformation parameter.

alpha_p.value	p-value of the Wald test for the estimated coefficient α.
sigma2_p.value	p-value of the Wald test for the estimated variance of the frailty term (σ_v).
etaR_p.value	p-values of the Wald test for the estimated regression coefficients for the link function $g(\cdot)$.
etaT_p.value	p-values of the Wald test for the estimated regression coefficients for the link function $h(\cdot)$.
y_0_p.value	p-value of the Wald test for the estimated biomarker intial level.
K_G0_p.value	p-value of the Wald test for the estimated biomarker growth parameter.
K_D0_p.value	p-value of the Wald test for the estimated biomarker decay parameter.
lambda_p.value	p-value of the Wald test for the estimated biomarker resistance to drug.
beta_p.value	p-values of the Wald test for the estimated regression coefficients.

Note

It is recommended to initialize the parameter values using the results from a corresponding reduced model (frailtyPenal for the recurrent and terminal part). See example.

Estimations of models with more than three random effects can be very long.

---

wts   *Identify weights*

Description

This is a special function used in the context of the joint frailty models for data from nested case-control studies. It specifies weights defined by using 'wts' function, and is used of 'frailtyPenal' formula for fitting joint models.

Usage

```
wts(x)
```

Arguments

x   A numeric variable which is supposed to indicate the weights

Value

x   A variable identified as weights

See Also

frailtyPenal

Examples

```
## Not run:

data(dataNCC)
modJoint.ncc <- frailtyPenal(Surv(t.start,t.stop,event)~cluster(id)+cov1
+cov2+terminal(death)+wts(ncc.wts), formula.terminalEvent=~cov1+cov2,
data=dataNCC,n.knots=8,kappa=c(1.6e+10, 5.0e+03),recurrentAG=TRUE, RandDist="LogN")

print(modJoint.ncc)

## End(Not run)
