

Package ‘htmltools’

December 7, 2022

Type Package

Title Tools for HTML

Version 0.5.4

Description Tools for HTML generation and output.

Depends R (>= 2.14.1)

Imports utils, digest, grDevices, base64enc, rlang (>= 0.4.10),
fastmap (>= 1.1.0), ellipsis

Suggests markdown, testthat, withr, Cairo, ragg, shiny

Enhances knitr

License GPL (>= 2)

URL <https://github.com/rstudio/htmltools>,

as.tags	<i>Convert a value to tags</i>
---------	--------------------------------

Description

An S3 method for converting arbitrary values to a value that can be used as the child of a tag or tagList. The default implementation simply calls `as.character()`.

Usage

```
as.tags(x, ...)
```

Arguments

x	Object to be converted.
...	Any additional parameters.

bindFillRole	<i>Allow tags to intelligently fill their container</i>
--------------	---

Description

Create fill containers and items. If a fill item is a direct child of a fill container, and that container has an opinionated height, then the item is allowed to grow and shrink to its container's size.

Usage

```
bindFillRole(
  x,
  ...,
  item = FALSE,
  container = FALSE,
  overwrite = FALSE,
  .cssSelector = NULL
)
```

Arguments

x	a <code>tag()</code> object. Can also be a valid <code>tagQuery()</code> input if <code>.cssSelector</code> is specified.
...	currently unused.
item	whether or not to treat x as a fill item.

container	whether or not to treat x as a fill container. Note this will the CSS display property on the tag to flex, which changes the way it does layout of it's direct children. Thus, one should be careful not to mark a tag as a fill container when it needs to rely on other display behavior.
overwrite	whether or not to override previous calls to <code>bindFillRole()</code> (e.g., to remove the item/container role from a tag).
.cssSelector	A character string containing a CSS selector for targeting particular (inner) tag(s) of interest. For more details on what selector(s) are supported, see tagAppendAttributes() .

Value

The original tag object (x) with additional attributes (and a [htmlDependency\(\)](#)).

Examples

```

tagz <- div(
  id = "outer",
  style = css(
    height = "600px",
    border = "3px red solid"
  ),
  div(
    id = "inner",
    style = css(
      height = "400px",
      border = "3px blue solid"
    )
  )
)

# Inner doesn't fill outer
if (interactive()) browsable(tagz)

tagz <- bindFillRole(tagz, container = TRUE)
tagz <- bindFillRole(tagz, item = TRUE, .cssSelector = "#inner")

# Inner does fill outer
if (interactive()) browsable(tagz)

```

browsable

Make an HTML object browsable

Description

By default, HTML objects display their HTML markup at the console when printed. `browsable` can be used to make specific objects render as HTML by default when printed at the console.

Usage

```
browsable(x, value = TRUE)
```

```
is.browsable(x)
```

Arguments

x	The object to make browsable or not.
value	Whether the object should be considered browsable.

Details

You can override the default browsability of an HTML object by explicitly passing `browse = TRUE` (or `FALSE`) to the `print` function.

Value

`browsable` returns `x` with an extra attribute to indicate that the value is browsable.

`is.browsable` returns `TRUE` if the value is browsable, or `FALSE` if not.

builder	<i>Create HTML tags</i>
---------	-------------------------

Description

Create an R object that represents an HTML tag. For convenience, common HTML tags (e.g., `<div>`) can be created by calling for their tag name directly (e.g., `div()`). To create less common HTML5 (or SVG) tags (e.g., `<article>`), use the tags list collection (e.g., `tags$article()`). To create other non HTML/SVG tags, use the lower-level `tag()` constructor.

Usage

```
tags
```

```
p(..., .noWS = NULL, .renderHook = NULL)
```

```
h1(..., .noWS = NULL, .renderHook = NULL)
```

```
h2(..., .noWS = NULL, .renderHook = NULL)
```

```
h3(..., .noWS = NULL, .renderHook = NULL)
```

```
h4(..., .noWS = NULL, .renderHook = NULL)
```

```
h5(..., .noWS = NULL, .renderHook = NULL)
```

```

h6(..., .noWS = NULL, .renderHook = NULL)
a(..., .noWS = NULL, .renderHook = NULL)
br(..., .noWS = NULL, .renderHook = NULL)
div(..., .noWS = NULL, .renderHook = NULL)
span(..., .noWS = NULL, .renderHook = NULL)
pre(..., .noWS = NULL, .renderHook = NULL)
code(..., .noWS = NULL, .renderHook = NULL)
img(..., .noWS = NULL, .renderHook = NULL)
strong(..., .noWS = NULL, .renderHook = NULL)
em(..., .noWS = NULL, .renderHook = NULL)
hr(..., .noWS = NULL, .renderHook = NULL)
tag(`_tag_name`, varArgs, .noWS = NULL, .renderHook = NULL)

```

Arguments

...	Tag attributes (named arguments) and children (unnamed arguments). A named argument with an NA value is rendered as a boolean attributes (see example). Children may include any combination of: <ul style="list-style-type: none"> • Other tags objects • <code>HTML()</code> strings • <code>htmlDependency()</code>s • Single-element atomic vectors • <code>list()</code>s containing any combination of the above
.noWS	Character vector used to omit some of the whitespace that would normally be written around this tag. Valid options include <code>before</code> , <code>after</code> , <code>outside</code> , <code>after-begin</code> , and <code>before-end</code> . Any number of these options can be specified.
.renderHook	A function (or list of functions) to call when the tag is rendered. This function should have at least one argument (the tag) and return anything that can be converted into tags via <code>as.tags()</code> . Additional hooks may also be added to a particular tag via <code>tagAddRenderHook()</code> .
_tag_name	A character string to use for the tag name.
varArgs	List of tag attributes and children.

Value

A `list()` with a `shiny.tag` class that can be converted into an HTML string via `as.character()` and saved to a file with `save_html()`.

See Also

[tagList\(\)](#), [withTags\(\)](#), [tagAppendAttributes\(\)](#), [tagQuery\(\)](#)

Examples

```
tags$html(
  tags$head(
    tags$title('My first page')
  ),
  tags$body(
    h1('My first heading'),
    p('My first paragraph, with some ', strong('bold'), ' text.'),
    div(
      id = 'myDiv', class = 'simpleDiv',
      'Here is a div with some attributes.'
    )
  )
)

# html5 <audio> with boolean control attribute
# https://www.w3.org/TR/html5/infrastructure.html#sec-boolean-attributes
tags$audio(
  controls = NA,
  tags$source(
    src = "myfile.wav",
    type = "audio/wav"
  )
)

# suppress the whitespace between tags
tags$span(
  tags$strong("I'm strong", .noWS="outside")
)
```

capturePlot

Capture a plot as a saved file

Description

Easily generates a .png file (or other graphics file) from a plotting expression.

Usage

```
capturePlot(
  expr,
  filename = tempfile(fileext = ".png"),
  device = defaultPngDevice(),
  width = 400,
```

```

    height = 400,
    res = 72,
    ...
  )

```

Arguments

expr	A plotting expression that generates a plot (or yields an object that generates a plot when printed, like a <code>ggplot2</code>). We evaluate this expression after activating the graphics device (<code>device</code>).
filename	The output filename. By default, a temp file with <code>.png</code> extension will be used; you should provide a filename with a different extension if you provide a non-PNG graphics device function.
device	A graphics device function; by default, this will be either <code>grDevices::png()</code> , <code>ragg::agg_png()</code> , or <code>Cairo::CairoPNG()</code> , depending on your system and configuration. See <code>defaultPngDevice()</code> .
width, height, res, ...	Additional arguments to the device function.

See Also

[plotTag\(\)](#) saves plots as a self-contained `` tag.

Examples

```

# Default settings
res <- capturePlot(plot(cars))

# View result
if (interactive()) browseURL(res)

# Clean up
unlink(res)

# Custom width/height
pngpath <- tempfile(fileext = ".png")
capturePlot(plot(pressure), pngpath, width = 800, height = 375)
if (interactive()) browseURL(pngpath)
unlink(pngpath)

# Use a custom graphics device (e.g., SVG)
if (capabilities("cairo")) {
  svgpath <- capturePlot(
    plot(pressure),
    tempfile(fileext = ".svg"),
    grDevices::svg,
    width = 8, height = 3.75
  )
  if (interactive()) browseURL(svgpath)
  unlink(svgpath)
}

```

copyDependencyToDir *Copy an HTML dependency to a directory*

Description

Copies an HTML dependency to a subdirectory of the given directory. The subdirectory name will be *name-version* (for example, "outputDir/jquery-1.11.0"). You may set `options(htmltools.dir.version = FALSE)` to suppress the version number in the subdirectory name.

Usage

```
copyDependencyToDir(dependency, outputDir, mustWork = TRUE)
```

Arguments

dependency	A single HTML dependency object.
outputDir	The directory in which a subdirectory should be created for this dependency.
mustWork	If TRUE and dependency does not point to a directory on disk (but rather a URL location), an error is raised. If FALSE then non-disk dependencies are returned without modification.

Details

In order for disk-based dependencies to work with static HTML files, it's generally necessary to copy them to either the directory of the referencing HTML file, or to a subdirectory of that directory. This function makes it easier to perform that copy.

Value

The dependency with its `src` value updated to the new location's absolute path.

See Also

[makeDependencyRelative\(\)](#) can be used with the returned value to make the path relative to a specific directory.

`css`*CSS string helper*

Description

Convenience function for building CSS style declarations (i.e. the string that goes into a style attribute, or the parts that go inside curly braces in a full stylesheet).

Usage

```
css(..., collapse_ = "")
```

Arguments

<code>...</code>	Named style properties, where the name is the property name and the argument is the property value. See Details for conversion rules.
<code>collapse_</code>	(Note that the parameter name has a trailing underscore character.) Character to use to collapse properties into a single string; likely "" (the default) for style attributes, and either "\n" or NULL for style blocks.

Details

CSS uses '-' (minus) as a separator character in property names, but this is an inconvenient character to use in an R function argument name. Instead, you can use '.' (period) and/or '_' (underscore) as separator characters. For example, `css(font.size = "12px")` yields `"font-size:12px;"`.

To mark a property as `!important`, add a '!' character to the end of the property name. (Since '!' is not normally a character that can be used in an identifier in R, you'll need to put the name in double quotes or backticks.)

Argument values will be converted to strings using `paste(collapse = " ")`. Any property with a value of `NULL` or `""` (after paste) will be dropped.

Examples

```
padding <- 6
css(
  font.family = "Helvetica, sans-serif",
  margin = paste0(c(10, 20, 10, 20), "px"),
  "padding!" = if (!is.null(padding)) padding
)
```

defaultPngDevice	<i>Determine the best PNG device for your system</i>
------------------	--

Description

Returns the best PNG-based graphics device for your system, in the opinion of the `htmltools` maintainers. On Mac, `grDevices::png()` is used; on all other platforms, either `ragg::agg_png()` or `Cairo::CairoPNG()` are used if their packages are installed. Otherwise, `grDevices::png()` is used.

Usage

```
defaultPngDevice()
```

Value

A graphics device function.

findDependencies	<i>Collect attached dependencies from HTML tag object</i>
------------------	---

Description

Walks a hierarchy of tags looking for attached dependencies.

Usage

```
findDependencies(tags, tagify = TRUE)
```

Arguments

tags	A tag-like object to search for dependencies.
tagify	Whether to tagify the input before searching for dependencies.

Value

A list of `htmlDependency()` objects.

HTML

Mark Characters as HTML

Description

Marks the given text as HTML, which means the [tag](#) functions will know not to perform HTML escaping on it.

Usage

```
HTML(text, ..., .noWS = NULL)
```

Arguments

text	The text value to mark with HTML
...	Any additional values to be converted to character and concatenated together
.noWS	Character vector used to omit some of the whitespace that would normally be written around this HTML. Valid options include before, after, and outside (equivalent to before and end).

Value

The input text, but marked as HTML.

Examples

```
e1 <- div(HTML("I like <u>turtles</u>"))
cat(as.character(e1))
```

htmlDependencies

HTML dependency metadata

Description

Gets or sets the HTML dependencies associated with an object (such as a tag).

Usage

```
htmlDependencies(x)

htmlDependencies(x) <- value

attachDependencies(x, value, append = FALSE)
```

Arguments

x	An object which has (or should have) HTML dependencies.
value	An HTML dependency, or a list of HTML dependencies.
append	If FALSE (the default), replace any existing dependencies. If TRUE, add the new dependencies to the existing ones.

Details

`attachDependencies` provides an alternate syntax for setting dependencies. It is similar to `local({htmlDependencies(x) <- value; x})`, except that if there are any existing dependencies, `attachDependencies` will add to them, instead of replacing them.

As of `htmltools` 0.3.4, HTML dependencies can be attached without using `attachDependencies`. Instead, they can be added inline, like a child object of a tag or `tagList()`.

Examples

```
# Create a JavaScript dependency
dep <- htmlDependency("jqueryui", "1.11.4", c(href="shared/jqueryui"),
  script = "jquery-ui.min.js")

# A CSS dependency
htmlDependency(
  "font-awesome", "4.5.0", c(href="shared/font-awesome"),
  stylesheet = "css/font-awesome.min.css"
)

# A few different ways to add the dependency to tag objects:
# Inline as a child of the div()
div("Code here", dep)
# Inline in a tagList
tagList(div("Code here"), dep)
# With attachDependencies
attachDependencies(div("Code here"), dep)
```

htmlDependency

Define an HTML dependency

Description

Define an HTML dependency (i.e. CSS and/or JavaScript bundled in a directory). HTML dependencies make it possible to use libraries like jQuery, Bootstrap, and d3 in a more composable and portable way than simply using `script`, `link`, and `style` tags.

Usage

```
htmlDependency(
  name,
  version,
  src,
  meta = NULL,
  script = NULL,
  stylesheet = NULL,
  head = NULL,
  attachment = NULL,
  package = NULL,
  all_files = TRUE
)
```

Arguments

name	Library name
version	Library version
src	Unnamed single-element character vector indicating the full path of the library directory. Alternatively, a named character string with one or more elements, indicating different places to find the library; see Details.
meta	Named list of meta tags to insert into document head
script	Script(s) to include within the document head (should be specified relative to the src parameter).
stylesheet	Stylesheet(s) to include within the document (should be specified relative to the src parameter).
head	Arbitrary lines of HTML to insert into the document head
attachment	Attachment(s) to include within the document head. See Details.
package	An R package name to indicate where to find the src directory when src is a relative path (see resolveDependencies()).
all_files	Whether all files under the src directory are dependency files. If FALSE, only the files specified in script, stylesheet, and attachment are treated as dependency files.

Details

Each dependency can be located on the filesystem, at a relative or absolute URL, or both. The location types are indicated using the names of the src character vector: file for filesystem directory, href for URL. For example, a dependency that was both on disk and at a URL might use `src = c(file=filepath, href=url)`.

script can be given as one of the following:

- a character vector specifying various scripts to include relative to the value of src. Each is expanded into its own `<script>` tag
- A named list with any of the following fields:

- src,
- integrity, &
- crossorigin,
- any other valid `<script>` attributes.

allowing the use of SRI to ensure the integrity of packages downloaded from remote servers.
Eg: `script = list(src = "min.js", integrity = "hash")`

- An unnamed list, containing a combination of named list with the fields mentioned previously, and strings. Eg:
 - `script = list(list(src = "min.js"), "util.js", list(src = "log.js"))`
 - `script = "pkg.js"` is equivalent to
 - `script = list(src = "pkg.js")`.

`attachment` can be used to make the indicated files available to the JavaScript on the page via URL. For each element of `attachment`, an element `<link id="DEPNAME-ATTACHINDEX-attachment" rel="attachment" href=` is inserted, where `DEPNAME` is name. The value of `ATTACHINDEX` depends on whether `attachment` is named or not; if so, then it's the name of the element, and if not, it's the 1-based index of the element. JavaScript can retrieve the URL using something like `document.getElementById(depname + "-" + index + "-attachment")`. Note that depending on the rendering context, the runtime value of the `href` may be an absolute, relative, or data URI.

`htmlDependency` should not be called from the top-level of a package namespace with absolute paths (or with paths generated by `system.file()`) and have the result stored in a variable. This is because, when a binary package is built, R will run `htmlDependency` and store the path from the building machine's in the package. This path is likely to differ from the correct path on a machine that downloads and installs the binary package. If there are any absolute paths, instead of calling `htmlDependency` at build-time, it should be called at run-time. This can be done by wrapping the `htmlDependency` call in a function.

Value

An object that can be included in a list of dependencies passed to `attachDependencies()`.

See Also

Use `attachDependencies()` to associate a list of dependencies with the HTML it belongs with. The shape of the `htmlDependency` object is described (in TypeScript code) [here](#).

htmlEscape

Escape HTML entities

Description

Escape HTML entities contained in a character vector so that it can be safely included as text or an attribute value within an HTML document

Usage

```
htmlEscape(text, attribute = FALSE)
```

Arguments

text	Text to escape
attribute	Escape for use as an attribute value

Value

Character vector with escaped text.

htmlPreserve	<i>Preserve HTML regions</i>
--------------	------------------------------

Description

Use "magic" HTML comments to protect regions of HTML from being modified by text processing tools.

Usage

```
htmlPreserve(x)

extractPreserveChunks(strval)

restorePreserveChunks(strval, chunks)
```

Arguments

x	A character vector of HTML to be preserved.
strval	Input string from which to extract/restore chunks.
chunks	The chunks element of the return value of extractPreserveChunks.

Details

Text processing tools like markdown and pandoc are designed to turn human-friendly markup into common output formats like HTML. This works well for most prose, but components that generate their own HTML may break if their markup is interpreted as the input language. The `htmlPreserve` function is used to mark regions of an input document as containing pure HTML that must not be modified. This is achieved by substituting each such region with a benign but unique string before processing, and undoing those substitutions after processing.

Value

`htmlPreserve` returns a single-element character vector with "magic" HTML comments surrounding the original text (unless the original text was empty, in which case an empty string is returned). `extractPreserveChunks` returns a list with two named elements: `value` is the string with the regions replaced, and `chunks` is a named character vector where the names are the IDs and the values are the regions that were extracted. `restorePreserveChunks` returns a character vector with the chunk IDs replaced with their original values.

Examples

```
# htmlPreserve will prevent "<script>alert(10*2*3);</script>"
# from getting an <em> tag inserted in the middle
markup <- paste(sep = "\n",
  "This is *emphasized* text in markdown.",
  htmlPreserve("<script>alert(10*2*3);</script>"),
  "Here is some more *emphasized text*."
)
extracted <- extractPreserveChunks(markup)
markup <- extracted$value
# Just think of this next line as Markdown processing
output <- gsub("\\*(.*?)\\*", "<em>\\1</em>", markup)
output <- restorePreserveChunks(output, extracted$chunks)
output
```

htmlTemplate

Process an HTML template

Description

Process an HTML template and return a tagList object. If the template is a complete HTML document, then the returned object will also have class `html_document`, and can be passed to the function [renderDocument\(\)](#) to get the final HTML text.

Usage

```
htmlTemplate(filename = NULL, ..., text_ = NULL, document_ = "auto")
```

Arguments

<code>filename</code>	Path to an HTML template file. Incompatible with <code>text_</code> .
<code>...</code>	Variable values to use when processing the template.
<code>text_</code>	A string to use as the template, instead of a file. Incompatible with <code>filename</code> .
<code>document_</code>	Is this template a complete HTML document (TRUE), or a fragment of HTML that is to be inserted into an HTML document (FALSE)? With "auto" (the default), auto-detect by searching for the string "<HTML>" within the template.

See Also

[renderDocument\(\)](#)

html_print	<i>Implementation of the print method for HTML</i>
------------	--

Description

Convenience method that provides an implementation of the `base::print()` method for HTML content.

Usage

```
html_print(  
  html,  
  background = "white",  
  viewer = getOption("viewer", utils::browseURL)  
)
```

Arguments

html	HTML content to print
background	Background color for web page
viewer	A function to be called with the URL or path to the generated HTML page. Can be NULL, in which case no viewer will be invoked.

Value

Invisibly returns the URL or path of the generated HTML page.

include	<i>Include Content From a File</i>
---------	------------------------------------

Description

Load HTML, text, or rendered Markdown from a file and turn into HTML.

Usage

```
includeHTML(path)  
  
includeText(path)  
  
includeMarkdown(path)  
  
includeCSS(path, ...)  
  
includeScript(path, ...)
```

Arguments

path	The path of the file to be included. It is highly recommended to use a relative path (the base path being the Shiny application directory), not an absolute path.
...	Any additional attributes to be applied to the generated tag.

Details

These functions provide a convenient way to include an extensive amount of HTML, textual, Markdown, CSS, or JavaScript content, rather than using a large literal R string.

Note

`includeText` escapes its contents, but does no other processing. This means that hard breaks and multiple spaces will be rendered as they usually are in HTML: as a single space character. If you are looking for preformatted text, wrap the call with `pre()`, or consider using `includeMarkdown` instead.

The `includeMarkdown` function requires the `markdown` package.

knitr_methods

Knitr S3 methods

Description

These S3 methods are necessary to allow HTML tags to print themselves in knitr/rmarkdown documents.

Usage

```
knit_print.shiny.tag(x, ..., inline = FALSE)
```

```
knit_print.html(x, ..., inline = FALSE)
```

```
knit_print.shiny.tag.list(x, ..., inline = FALSE)
```

Arguments

x	Object to <code>knit_print</code>
...	Additional <code>knit_print</code> arguments
inline	Whether or not the code chunk is inline.

makeDependencyRelative

Make an absolute dependency relative

Description

Change a dependency's absolute path to be relative to one of its parent directories.

Usage

```
makeDependencyRelative(dependency, basepath, mustWork = TRUE)
```

Arguments

dependency	A single HTML dependency with an absolute path.
basepath	The path to the directory that dependency should be made relative to.
mustWork	If TRUE and dependency does not point to a directory on disk (but rather a URL location), an error is raised. If FALSE then non-disk dependencies are returned without modification.

Value

The dependency with its src value updated to the new location's relative path.

If basepath did not appear to be a parent directory of the dependency's directory, an error is raised (regardless of the value of mustWork).

See Also

[copyDependencyToDir\(\)](#)

parseCssColors

Parse CSS color strings

Description

Parses/normalizes CSS color strings, and returns them as strings in "#RRGGBB" and/or "#RRGGBBAA" format. Understands hex colors in 3, 4, 6, and 8 digit forms, rgb()/rgba(), hsl()/hsla(), and color keywords.

Usage

```
parseCssColors(str, mustWork = TRUE)
```

Arguments

str	CSS color strings
mustWork	If true, invalid color strings will cause an error; if false, then the result will contain NA for invalid colors.

Details

Note that `parseCssColors` may return colors in #RRGGBBAA format. Such values are not understood by Internet Explorer, and must be converted to `rgba(red, green, blue, alpha)` format to be safe for the web.

Value

A vector of strings in #RRGGBB or #RRGGBBAA format (the latter is only used for colors whose alpha values are less than FF), or NA for invalid colors when `mustWork` is false. Such strings are suitable for use in plots, or parsing with `col2rgb()` (be sure to pass `alpha = TRUE` to prevent the alpha channel from being discarded).

Examples

```
parseCssColors(c(
  "#0d6efd",
  "#DC35457F",
  "rgb(32,201,151)",
  " rgba( 23 , 162 , 184 , 0.5 ) ",
  "hsl(261, 51%, 51%)",
  "cornflowerblue"
))
```

plotTag

Capture a plot as a self-contained tag

Description

Capture a plot as a self-contained tag

Usage

```
plotTag(
  expr,
  alt,
  device = defaultPngDevice(),
  width = 400,
  height = 400,
  pixelratio = 2,
  mimeType = "image/png",
  deviceArgs = list(),
```

```

  attribs = list(),
  suppressSize = c("none", "x", "y", "xy")
)

```

Arguments

<code>expr</code>	A plotting expression that generates a plot (or yields an object that generates a plot when printed, like a <code>ggplot2</code>).
<code>alt</code>	A single-element character vector that contains a text description of the image. This is used by accessibility tools, such as screen readers for vision impaired users.
<code>device</code>	A graphics device function; by default, this will be either <code>grDevices::png()</code> , <code>ragg::agg_png()</code> , or <code>Cairo::CairoPNG()</code> , depending on your system and configuration. See <code>defaultPngDevice()</code> .
<code>width, height</code>	The width/height that the generated tag should be displayed at, in logical (browser) pixels.
<code>pixelratio</code>	Indicates the ratio between physical and logical units of length. For PNGs that may be displayed on high-DPI screens, use 2; for graphics devices that express width/height in inches (like <code>grDevices::svg()</code> , try 1/72 or 1/96.
<code>mimeType</code>	The MIME type associated with the device. Examples are <code>image/png</code> , <code>image/tiff</code> , <code>image/svg+xml</code> .
<code>deviceArgs</code>	A list of additional arguments that should be included when the device function is invoked.
<code>attribs</code>	A list of additional attributes that should be included on the generated <code></code> (e.g. <code>id</code> , <code>class</code>).
<code>suppressSize</code>	By default, <code>plotTag</code> will include a <code>style</code> attribute with <code>width</code> and <code>height</code> properties specified in pixels. If you'd rather specify the image size using other methods (like responsive CSS rules) you can use this argument to suppress <code>width</code> (" <code>x</code> "), <code>height</code> (" <code>y</code> "), or both (" <code>xy</code> ") properties.

Value

A `browsable()` HTML `` tag object. Print it at the console to preview, or call `as.character()` on it to view the HTML source.

See Also

`capturePlot()` saves plots as an image file.

Examples

```

img <- plotTag({
  plot(cars)
}, "A plot of the 'cars' dataset", width = 375, height = 275)

if (interactive()) img

```

```

if (interactive() && capabilities("cairo")) {
  plotTag(
    plot(pressure), "A plot of the 'pressure' dataset",
    device = grDevices::svg, width = 375, height = 275, pixelratio = 1/72,
    mimeType = "image/svg+xml"
  )
}

```

```
print.shiny.tag      Print method for HTML/tags
```

Description

S3 method for printing HTML that prints markup or renders HTML in a web browser.

Usage

```

## S3 method for class 'shiny.tag'
print(x, browse = is.browsable(x), ...)

## S3 method for class 'html'
print(x, ..., browse = is.browsable(x))

```

Arguments

x	The value to print.
browse	If TRUE, the HTML will be rendered and displayed in a browser (or possibly another HTML viewer supplied by the environment via the viewer option). If FALSE then the HTML object's markup will be rendered at the console.
...	Additional arguments passed to print.

```
renderDependencies  Create HTML for dependencies
```

Description

Create the appropriate HTML markup for including dependencies in an HTML document.

Usage

```

renderDependencies(
  dependencies,
  srcType = c("href", "file"),
  encodeFunc = urlEncodePath,
  hrefFilter = identity
)

```

Arguments

dependencies	A list of <code>htmlDependency</code> objects.
srcType	The type of src paths to use; valid values are <code>file</code> or <code>href</code> .
encodeFunc	The function to use to encode the path part of a URL. The default should generally be used.
hrefFilter	A function used to transform the final, encoded URLs of script and stylesheet files. The default should generally be used.

Value

An `HTML()` object suitable for inclusion in the head of an HTML document.

renderDocument	<i>Render an <code>html_document</code> object</i>
----------------	--

Description

This function renders `html_document` objects, and returns a string with the final HTML content. It calls the `renderTags()` function to convert any `shiny.tag` objects to HTML. It also finds any any web dependencies (created by `htmlDependency()`) that are attached to the tags, and inserts those. To do the insertion, this function finds the string "`<!-- HEAD_CONTENT -->`" in the document, and replaces it with the web dependencies.

Usage

```
renderDocument(x, deps = NULL, processDep = identity)
```

Arguments

x	An object of class <code>html_document</code> , typically generated by the <code>htmlTemplate()</code> function.
deps	Any extra web dependencies to add to the html document. This can be an object created by <code>htmlDependency()</code> , or a list of such objects. These dependencies will be added first, before other dependencies.
processDep	A function that takes a "raw" <code>html_dependency</code> object and does further processing on it. For example, when <code>renderDocument</code> is called from Shiny, the function <code>shiny::createWebDependency()</code> is used; it modifies the href and tells Shiny to serve a particular path on the filesystem.

Value

An `HTML()` string, with UTF-8 encoding.

`renderTags`*Render tags into HTML*

Description

Renders tags (and objects that can be converted into tags using `as.tags()`) into HTML. (Generally intended to be called from web framework libraries, not directly by most users—see `print.html()` for higher level rendering.)

Usage

```
renderTags(x, singletons = character(0), indent = 0)
```

```
doRenderTags(x, indent = 0)
```

Arguments

<code>x</code>	Tag object(s) to render
<code>singletons</code>	A list of singleton signatures to consider already rendered; any matching singletons will be dropped instead of rendered. (This is useful (only?) for incremental rendering.)
<code>indent</code>	Initial indent level, or FALSE if no indentation should be used.

Details

`doRenderTags` is intended for very low-level use; it ignores render hooks, singletons, head, and dependency handling, and simply renders the given tag objects as HTML. Please use `renderTags()` if `x` has not already handled its dependencies and render hooks.

Value

`renderTags` returns a list with the following variables:

- `head`: An [HTML\(\)](#) string that should be included in `<head>`.
- `singletons`: Character vector of singleton signatures that are known after rendering.
- `dependencies`: A list of [resolved htmlDependency\(\)](#) objects.
- `html`: An [HTML\(\)](#) string that represents the main HTML that was rendered.

`doRenderTags` returns a simple [HTML\(\)](#) string.

resolveDependencies	<i>Resolve a list of dependencies</i>
---------------------	---------------------------------------

Description

Given a list of dependencies, removes any redundant dependencies (based on name equality). If multiple versions of a dependency are found, the copy with the latest version number is used.

Usage

```
resolveDependencies(dependencies, resolvePackageDir = TRUE)
```

Arguments

dependencies	A list of htmlDependency() objects.
resolvePackageDir	Whether to resolve the relative path to an absolute path via system.file() when the package attribute is present in a dependency object.

Value

dependencies A list of [htmlDependency\(\)](#) objects with redundancies removed.

save_html	<i>Save an HTML object to a file</i>
-----------	--------------------------------------

Description

Save the specified HTML object to a file, copying all of it's dependencies to the directory specified via libdir.

Usage

```
save_html(html, file, background = "white", libdir = "lib", lang = "en")
```

Arguments

html	HTML content to print
file	File path or connection. If a file path containing a sub-directory, the sub-directory must already exist.
background	Background color for web page
libdir	Directory to copy dependencies to
lang	Value of the <html> lang attribute

singleton	<i>Include content only once</i>
-----------	----------------------------------

Description

Use `singleton` to wrap contents (tag, text, HTML, or lists) that should be included in the generated document only once, yet may appear in the document-generating code more than once. Only the first appearance of the content (in document order) will be used.

Usage

```
singleton(x, value = TRUE)
```

```
is.singleton(x)
```

Arguments

x	A <code>tag()</code> , text, <code>HTML()</code> , or list.
value	Whether the object should be a singleton.

singleton_tools	<i>Singleton manipulation functions</i>
-----------------	---

Description

Functions for manipulating `singleton()` objects in tag hierarchies. Intended for framework authors.

Usage

```
surroundSingletons(ui)
```

```
takeSingletons(ui, singletons = character(0), desingleton = TRUE)
```

Arguments

ui	Tag object or lists of tag objects. See <code>builder</code> topic.
singletons	Character vector of singleton signatures that have already been encountered (i.e. returned from previous calls to <code>takeSingletons</code>).
desingleton	Logical value indicating whether singletons that are encountered should have the singleton attribute removed.

Value

surroundSingletons preprocesses a tag object by changing any singleton X into `<!--SHINY.SINGLETON[sig]-->X'<!--/S` where sig is the sha1 of X, and X' is X minus the singleton attribute.

takeSingletons returns a list with the elements ui (the processed tag objects with any duplicate singleton objects removed) and singletons (the list of known singleton signatures).

subtractDependencies *Subtract dependencies*

Description

Remove a set of dependencies from another list of dependencies. The set of dependencies to remove can be expressed as either a character vector or a list; if the latter, a warning can be emitted if the version of the dependency being removed is later than the version of the dependency object that is causing the removal.

Usage

```
subtractDependencies(dependencies, remove, warnOnConflict = TRUE)
```

Arguments

dependencies A list of [htmlDependency\(\)](#) objects from which dependencies should be removed.

remove A list of [htmlDependency\(\)](#) objects indicating which dependencies should be removed, or a character vector indicating dependency names.

warnOnConflict If TRUE, a warning is emitted for each dependency that is removed if the corresponding dependency in remove has a lower version number. Has no effect if remove is provided as a character vector.

Value

A list of [htmlDependency\(\)](#) objects that don't intersect with remove.

suppressDependencies *Suppress web dependencies*

Description

This suppresses one or more web dependencies. It is meant to be used when a dependency (like a JavaScript or CSS file) is declared in raw HTML, in an HTML template.

Usage

```
suppressDependencies(...)
```

Arguments

... Names of the dependencies to suppress. For example, "jquery" or "bootstrap".

See Also

[htmlTemplate\(\)](#) for more information about using HTML templates.

[htmlDependency\(\)](#)

tagAddRenderHook	<i>Modify a tag prior to rendering</i>
------------------	--

Description

Adds a hook to call on a [tag\(\)](#) object when it is rendered as HTML (with, for example, [print\(\)](#), [renderTags\(\)](#), [as.tags\(\)](#), etc).

Usage

```
tagAddRenderHook(tag, func, replace = FALSE)
```

Arguments

tag	A tag() object.
func	A function (<i>hook</i>) to call when the tag is rendered. This function should have at least one argument (the tag) and return anything that can be converted into tags via as.tags() .
replace	If TRUE, the previous hooks will be removed. If FALSE, func is appended to the previous hooks.

Details

The primary motivation for [tagAddRenderHook\(\)](#) is to create tags that can change their attributes (e.g., change CSS classes) depending upon the context in which they're rendered (e.g., use one set of CSS classes in one a page layout, but a different set in another page layout). In this situation, [tagAddRenderHook\(\)](#) is preferable to [tagFunction\(\)](#) since the latter is more a "black box" in the sense that you don't know anything about the tag structure until it's rendered.

Value

A [tag\(\)](#) object with a `.renderHooks` field containing a list of functions (e.g. `func`). When the return value is *rendered* (such as with [as.tags\(\)](#)), these functions will be called just prior to writing the HTML.

See Also

[tagFunction\(\)](#)

Examples

```

# Have a place holder div and return a span instead
obj <- div("example", .renderHook = function(x) {
  x$name <- "span"
  x
})
obj$name # "div"
print(obj) # Prints as a `span`

# Add a class to the tag
# Should print a `span` with class `extra`
spanExtra <- tagAddRenderHook(obj, function(x) {
  tagAppendAttributes(x, class = "extra")
})
spanExtra

# Replace the previous render method
# Should print a `div` with class `extra`
divExtra <- tagAddRenderHook(obj, replace = TRUE, function(x) {
  tagAppendAttributes(x, class = "extra")
})
divExtra

# Add more child tags
spanExtended <- tagAddRenderHook(obj, function(x) {
  tagAppendChildren(x, " ", tags$strong("bold text"))
})
spanExtended

# Add a new html dependency
newDep <- tagAddRenderHook(obj, function(x) {
  fa <- htmlDependency(
    "font-awesome", "4.5.0", c(href="shared/font-awesome"),
    stylesheet = "css/font-awesome.min.css")
  attachDependencies(x, fa, append = TRUE)
})
# Also add a jqueryui html dependency
htmlDependencies(newDep) <- htmlDependency(
  "jqueryui", "1.11.4", c(href="shared/jqueryui"),
  script = "jquery-ui.min.js")
# At render time, both dependencies will be found
renderTags(newDep)$dependencies

# Ignore the original tag and return something completely new.
newObj <- tagAddRenderHook(obj, function(x) {
  tags$p("Something else")
})
newObj

```

Description

Append (`tagAppendAttributes()`), check existence (`tagHasAttribute()`), and obtain the value (`tagGetAttribute()`) of HTML attribute(s).

Usage

```
tagAppendAttributes(tag, ..., .cssSelector = NULL)
```

```
tagHasAttribute(tag, attr)
```

```
tagGetAttribute(tag, attr)
```

Arguments

<code>tag</code>	a tag object.
<code>...</code>	a collection of attributes.
<code>.cssSelector</code>	A character string containing a CSS selector for targeting particular (inner) tags of interest. At the moment, only a combination of type (e.g, <code>div</code>), class (e.g., <code>.my-class</code>), id (e.g., <code>#myID</code>), and universal (*) selectors within a given simple selector is supported. Note, if <code>.cssSelector</code> is used, the returned tags will have their <code>\$children</code> fields flattened to a single <code>list()</code> via tagQuery() .
<code>attr</code>	The name of an attribute.

See Also

[tagAppendChildren\(\)](#), [tagQuery\(\)](#)

Examples

```
html <- div(a())
tagAppendAttributes(html, class = "foo")
tagAppendAttributes(html, .cssSelector = "a", class = "bar")

tagHasAttribute(div(foo = "bar"), "foo")
tagGetAttribute(div(foo = "bar"), "foo")
```

tagAppendChild	<i>Modify tag contents</i>
----------------	----------------------------

Description

Modify the contents (aka children) of a [tag](#) object.

Usage

```

tagAppendChild(tag, child, .cssSelector = NULL)

tagAppendChildren(tag, ..., .cssSelector = NULL, list = NULL)

tagSetChildren(tag, ..., .cssSelector = NULL, list = NULL)

tagInsertChildren(tag, after, ..., .cssSelector = NULL, list = NULL)

```

Arguments

tag	a tag object.
child	A child element to append to a parent tag.
.cssSelector	A character string containing a CSS selector for targeting particular (inner) tags of interest. At the moment, only a combination of type (e.g, div), class (e.g., .my-class), id (e.g., #myID), and universal (*) selectors within a given simple selector is supported. Note, if .cssSelector is used, the returned tags will have their \$children fields flattened to a single list() via tagQuery() .
...	a collection of child elements.
list	Deprecated. Use !!! instead to splice into
after	an integer value (i.e., subscript) referring to the child position to append after.

See Also

[tagAppendAttributes\(\)](#), [tagQuery\(\)](#)

Examples

```

html <- div(a(), h1())
tagAppendChild(html, span())
tagAppendChild(html, .cssSelector = "a", span())

tagAppendChildren(html, span(), p())
tagAppendChildren(html, .cssSelector = "a", span(), p())

tagSetChildren(html, span(), p())

tagInsertChildren(html, after = 1, span(), p())

```

tagFunction

Tag function

Description

Create 'lazily' rendered HTML [tags](#) (and/or [htmlDependencies\(\)](#)).

Usage

```
tagFunction(func)
```

Arguments

func a function with no arguments that returns HTML tags and/or dependencies.

Details

When possible, use [tagAddRenderHook\(\)](#) to provide both a tag structure and utilize a render function.

See Also

[tagAddRenderHook\(\)](#)

Examples

```
myDivDep <- tagFunction(function() {
  if (isTRUE(getOption("useDep", TRUE))) {
    htmlDependency(
      name = "lazy-dependency",
      version = "1.0", src = ""
    )
  }
})
myDiv <- attachDependencies(div(), myDivDep)
renderTags(myDiv)
withr::with_options(list(useDep = FALSE), renderTags(myDiv))
```

tagList

Create a list of tags

Description

Create a `list()` of `tags` with methods for `print()`, `as.character()`, etc.

Usage

```
tagList(...)
```

Arguments

... A collection of `tags`.

Examples

```

tagList(
  h1("Title"),
  h2("Header text"),
  p("Text here")
)

```

tagQuery

*Query and modify HTML tags***Description****[Experimental]**

tagQuery() provides a **jQuery** inspired interface for querying and modifying tag() (and tagList()) objects.

Usage

```
tagQuery(tags)
```

Arguments

tags A tag(), tagList(), or list() of tags.

Value

A class with methods that are described below. This class can't be used directly inside other tag() or a renderTags() context, but underlying HTML tags may be extracted via \$allTags() or \$selectedTags().

Altered Tag structure

For performance reasons, the input tag structure to tagQuery() will be altered into a consistently expected shape.

Some alterations include:

- tags flattening their \$children fields into a single list()
- tags relocating any attribute html_dependency() to be located in \$children'
- tagList()-like structures relocating any attribute html dependency to be a entry in its list structure.

While the resulting tag shape has possibly changed, tagQuery()'s' resulting tags will still render to the same HTML value (ex: renderTags()) and HTML dependencies (ex: findDependencies()).

Vignette

To get started with using `tagQuery()`, visit <https://rstudio.github.io/htmltools/articles/tagQuery.html>.

Methods

Unless otherwise stated, `tagQuery()` methods accept a character vector as input.

Query methods:

Query methods identify particular subsets of the root tag using CSS selectors (or R functions).

Children:

- `$find(cssSelector)`: Get the descendants of each selected tag, filtered by a `cssSelector`.
- `$children(cssSelector = NULL)`: Get the direct children of each selected tag, optionally filtered by a `cssSelector`.

Siblings:

- `siblings(cssSelector = NULL)`: Get the siblings of each selected tag, optionally filtered by a `cssSelector`.

Parents:

- `$parent(cssSelector = NULL)`: Get the parent of each selected tag, optionally filtered by a `cssSelector`.
- `$parents(cssSelector = NULL)`: Get the ancestors of each selected tag, optionally filtered by a `cssSelector`.
- `$closest(cssSelector = NULL)`: For each selected tag, get the closest ancestor tag (including itself) satisfying a `cssSelector`. If `cssSelector = NULL`, it is equivalent to calling `$selectedTags()`.

Custom filter:

- `$filter(fn)`: Filter the selected tags to those for which `fn(x, i)` returns `TRUE`. In addition to an R function with two arguments (the selected tag `x` and the index `i`), `fn` may also be a valid CSS selector.

Length:

- `$length()`: Number of tags that have been selected.

Reset:

- `$resetSelected()`: Reset selected tags to the `$root()` tag. Useful in combination with `$replaceWith()` since it empties the selection.

Modify methods:

Unlike query methods, modify methods modify the `tagQuery()` object.

Attributes:

- `$addClass(class)`: Adds class(es) to each selected tag.
- `$removeClass(class)`: Removes class(es) to each selected tag.
- `$toggleClass(class)`: Adds class(es) that don't already exist and removes class(es) that do already exist (for each selected tag).
- `$hasClass(class)`: Does each selected tag have all the provided class(es)?
- `$addAttrs(...)`: Add a set of attributes to each selected tag.

- `$removeAttrs(attrs)`: Remove a set of attributes from each selected tag.
- `$hasAttrs(attr)`: Do each selected tags have all of the attributes?

Children:

- `$append(...)`: For each selected tag, insert ... **after** any existing children.
- `$prepend(...)`: For each selected tag, insert ... **before** any existing children.

Siblings:

- `$after(...)`: Add all ... objects as siblings after each of the selected tags.
- `$before(...)`: Add all ... objects as siblings before each of the selected tags.

Custom:

- `$each(fn)`: Modify each selected tag with a function `fn`. `fn` should accept two arguments: the first is the selected tag and second is the selected tags position index. Since the selected tag is a reference, any modifications to it will also modify the `tagQuery()` object.

Replace methods:

- `$replaceWith(...)`: Replace all selected tags with ... in the root tag and clear the selection.
- `$remove(...)`: Remove all selected tags from the root tag and clear the current selection.
- `$empty()`: Remove any children of each selected tag. Use this method before calling `$append(...)` to replace the children of each selected tag, with other content.

Extract HTML tags:

- `$allTags()`: Return the (possibly modified) root tags.
- `$selectedTags()`: Return a `tagList()` of the currently selected tags.

Examples

```
tagQ <- tagQuery(div(a()))
tagQ$find("a")$addClass("foo")
tagQ
```

To learn more, visit <https://rstudio.github.io/htmltools/articles/tagQuery.html>

urlEncodePath

Encode a URL path

Description

Encode characters in a URL path. This is the same as `utils::URLencode()` with `reserved = TRUE` except that `/` is preserved.

Usage

```
urlEncodePath(x)
```

Arguments

`x` A character vector.

validateCssUnit	<i>Validate proper CSS formatting of a unit</i>
-----------------	---

Description

Checks that the argument is valid for use as a CSS unit of length.

Usage

```
validateCssUnit(x)
```

Arguments

x	The unit to validate. Will be treated as a number of pixels if a unit is not specified.
---	---

Details

NULL and NA are returned unchanged.

Single element numeric vectors are returned as a character vector with the number plus a suffix of "px".

Single element character vectors must be "auto", "fit-content" or "inherit", a number, or a length calculated by the "calc" CSS function. If the number has a suffix, it must be valid: px, \%, ch, em, rem, pt, in, cm, mm, ex, pc, vh, vw, vmin, or vmax. If the number has no suffix, the suffix "px" is appended.

Any other value will cause an error to be thrown.

Value

A properly formatted CSS unit of length, if possible. Otherwise, will throw an error.

Examples

```
validateCssUnit("10%")
validateCssUnit(400) #treated as '400px'
```

withTags

*Evaluate an expression using tags***Description**

This function makes it simpler to write HTML-generating code. Instead of needing to specify tags each time a tag function is used, as in `tags$div()` and `tags$p()`, code inside `withTags` is evaluated with tags searched first, so you can simply use `div()` and `p()`.

Usage

```
withTags(code, .noWS = NULL)
```

Arguments

<code>code</code>	A set of tags.
<code>.noWS</code>	Default whitespace behavior for all tags within this call to <code>withTags()</code> . Setting <code>.noWS</code> on an individual tag function inside <code>withTags()</code> will override the default. See tag() for complete options.

Details

If your code uses an object which happens to have the same name as an HTML tag function, such as `source()` or `summary()`, it will call the tag function. To call the intended (non-tags function), specify the namespace, as in `base::source()` or `base::summary()`.

Examples

```
# Using tags$ each time
tags$div(class = "myclass",
  tags$h3("header"),
  tags$p("text")
)

# Equivalent to above, but using withTags
withTags(
  div(class = "myclass",
    h3("header"),
    p("text")
  )
)

# Setting .noWS for all tags in withTags()
withTags(
  div(
    class = "myclass",
    h3("header"),
    p("One", strong(span("two")), "three")
  ),
```

```
    .noWS = c("outside", "inside")  
  )
```
