

Package ‘mistral’

October 13, 2022

Type Package

Title Methods in Structural Reliability

Version 2.2.1

Author Clement WALTER, Gilles DEFAUX, Bertrand IOOSS, Vincent MOUTOUSSAMY with contributions from Nicolas BOUSQUET, Claire CANNAMELA and Paul LEMAITRE

Maintainer Bertrand Iooss <biooss@yahoo.fr>

Depends R (>= 3.0.0)

Imports e1071, Matrix, mvtnorm, ggplot2, doParallel, foreach, iterators, DiceKriging, emoa, quadprog, Rcpp

Suggests microbenchmark, deSolve, scatterplot3d, KrigInv, rgenoud, kernlab, knitr, rmarkdown, markdown

Description Various reliability analysis methods for rare event inference: 1) computing failure probability (probability that the output of a numerical model exceeds a threshold), 2) computing quantile of low or high-order, 3) Wilks formula to compute quantile(s) from a sample or the size of the required i.i.d. sample.

Description

Provide tools for structural reliability analysis (failure probability, quantile).

Details

Package: mistral
Type: Package
Version: 2.2.1 Date: 2016-12-21
License: CeCILL

This package provides tools for structural reliability analysis:

- Calculate failure probability with FORM method and importance sampling.
- Calculate failure probability with crude Monte Carlo method
- Calculate failure probability with Subset Simulation algorithm
- Calculate failure probability with Monotonic Reliability Methods (MRM)
- Calculate failure probability with metamodel based algorithms : AKMCS, SMART and MetaIS
- Calculate failure probability with a metamodel based Subset Simulation : S2MART
- Wilks formula: Compute a quantile (or tolerance interval) with a given confidence level from a i.i.d. sample,
- Wilks formula: Compute the minimal sample size to estimate a quantile with a given confidence level,
- Calculate a quantile under monotonicity constraints

Author(s)

AKMCS

Active learning reliability method combining Kriging and Monte Carlo Simulation

Description

Estimate a failure probability with the AKMCS method.

Usage

```
AKMCS(
  dimension,
  lsf,
```

```

N = 5e+05,
N1 = 10 * dimension,
Nmax = 200,
Nmin = 2,
X = NULL,
y = NULL,
failure = 0,
precision = 0.05,
bayesian = TRUE,
compute.PPP = FALSE,
meta_model = NULL,
kernel = "matern5_2",
learn_each_train = TRUE,
crit_min = 2,
lower.tail = TRUE,
limit_fun_MH = NULL,
failure_MH = 0,
sampling_strategy = "MH",
first_DOE = "Gaussian",
seeds = NULL,
seeds_eval = limit_fun_MH(seeds),
burnin = 30,
plot = FALSE,
limited_plot = FALSE,
add = FALSE,
output_dir = NULL,
verbose = 0
)

```

Arguments

dimension	dimension of the input space.
lsf	the function defining the failure/safety domain.
N	Monte-Carlo population size.
N1	size of the first DOE.
Nmax	maximum number of calls to the LSF.
Nmin	minimum number of calls during enrichment step.
X	coordinates of already known points.
y	value of the LSF on these points.
failure	failure threshold.
precision	maximum desired cov on the Monte-Carlo estimate.
bayesian	estimate the conditional expectation $E_X [P[\text{meta}(X) < \text{failure}]]$.
compute.PPP	to simulate a Poisson process at each iteration to estimate the conditional expectation and the SUR criteria based on the conditional variance: h (average probability of misclassification at level failure) and I (integral of h over the whole interval $[\text{failure}, \text{inf}]$)

<code>meta_model</code>	provide here a kriging metamodel from km if wanted.
<code>kernel</code>	specify the kernel to use for km.
<code>learn_each_train</code>	specify if kernel parameters are re-estimated at each train.
<code>crit_min</code>	minimum value of the criteria to be used for refinement.
<code>lower.tail</code>	as for pxxxx functions, TRUE for estimating $P(\text{lsf}(X) < \text{failure})$, FALSE for $P(\text{lsf}(X) > \text{failure})$
<code>limit_fun_MH</code>	define an area of exclusion with a limit function.
<code>failure_MH</code>	the threshold for the <code>limit_fun_MH</code> function.
<code>sampling_strategy</code>	either MH for Metropolis-Hastings or AR for accept-reject.
<code>first_DoE</code>	either Gaussian or Uniform, to specify the population on which clustering is done. Set to "No" for no initial DoE (use together with a first DoE given in X for instance).
<code>seeds</code>	if some points are already known to be in the appropriate subdomain.
<code>seeds_eval</code>	value of the metamodel on these points.
<code>burnin</code>	burnin parameter for MH.
<code>plot</code>	set to TRUE for a full plot, ie refresh at each iteration.
<code>limited_plot</code>	set to TRUE for a final plot with final DOE, metamodel and LSF.
<code>add</code>	if plots are to be added to a current device.
<code>output_dir</code>	if plots are to be saved in jpeg in a given directory.
<code>verbose</code>	either 0 for almost no output, 1 for medium size output and 2 for all outputs.

Details

AKMCS strategy is based on a original Monte-Carlo population which is classified with a kriging-based metamodel. This means that no sampling is done during refinements steps. Indeed, it tries to classify this Monte-Carlo population with a confidence greater than a given value, for instance 'distance' to the failure should be greater than `crit_min` standard deviation.

Thus, while this criterion is not verified, the point minimizing it is added to the learning database and then evaluated.

Finally, once all points are classified or when the maximum number of calls has been reached, crude Monte-Carlo is performed. A final test controlling the size of this population regarding the targeted coefficient of variation is done; if it is too small then a new population of sufficient size (considering ordre of magnitude of found probability) is generated, and algorithm run again.

Value

An object of class `list` containing the failure probability and some more outputs as described below:

<code>p</code>	the estimated failure probability.
<code>cov</code>	the coefficient of variation of the Monte-Carlo probability estimate.

Ncall	the total number of calls to the lsf.
X	the final learning database, ie. all points where lsf has been calculated.
y	the value of the lsf on the learning database.
h	the sequence of the estimated relative SUR criteria.
I	the sequence of the estimated integrated SUR criteria.
meta_fun	the metamodel approximation of the lsf. A call output is a list containing the value and the standard deviation.
meta_model	the final metamodel. An S4 object from DiceKriging . Note that the algorithm enforces the problem to be the estimation of $P[\text{lsf}(X) < \text{failure}]$ and so using 'predict' with this object will return inverse values if <code>lower.tail==FALSE</code> ; in this scope prefer using directly <code>meta_fun</code> which handles this possible issue.
points	points in the failure domain according to the metamodel.
meta_eval	evaluation of the metamodel on these points.
z_meta	if <code>plot==TRUE</code> , the evaluation of the metamodel on the plot grid.

Note

Problem is supposed to be defined in the standard space. If not, use [UtoX](#) to do so. Furthermore, each time a set of vector is defined as a matrix, 'nrow' = dimension and 'ncol' = number of vector to be consistent with `as.matrix` transformation of a vector.

Algorithm calls `lsf(X)` (where X is a matrix as defined previously) and expects a vector in return. This allows the user to optimise the computation of a batch of points, either by vectorial computation, or by the use of external codes (optimised C or C++ codes for example) and/or parallel computation; see examples in [MonteCarlo](#).

cov = sqrt((1-P)/(N*P))

## End(Not run)
```

Description

This function runs the Bayesian Moving Particles algorithm for estimating extreme probability and quantile.

Usage

```

BMP(
  dimension,
  lsf,
  q,
  N = 1000,
  N.final = N,
  N.iter = 30,
  adaptive = FALSE,
  N.DoE = 5 * dimension,
  firstDoE = "uniform",
  radius = qnorm(1e-10, lower.tail = FALSE),
  X,
  Y,
  covariance = NULL,
  learn_each_train = Inf,
  km.param = list(nugget.estim = TRUE, multistart = 1, optim.method = "BFGS", coef.trend
    = q),
  burnin = 20,
  fast = TRUE,
  sur = list(integrated = TRUE, r = 1, approx.pnorm = FALSE),
  lower.tail = TRUE,
  save.dir,
  plot = FALSE,
  plot.lsf = TRUE,
  plot.lab = c("x_1", "x_2"),
  chi2 = FALSE,
  verbose = 1,
  breaks
)

```

Arguments

dimension	the dimension of the input space.
lsf	the function defining the RV of interest $Y = \text{lsf}(X)$.
q	a given quantile to estimate the corresponding probability.
N	the total number of Poisson processes during the refinement step.
N.final	the total number of Poisson processes for the final alpha estimate.
N.iter	the total number of iteration of the algorithm, ie that total number of calls to the lsf will be $N.\text{DoE} + N.\text{iter} * r$.
adaptive	if the algorithm should stop automatically if the stopping criterion is verified, precisely the mean probability of misclassification of the particles being over a given threshold.
N.DoE	the number of points for the initial Design of Experiment
firstDoE	default is "uniform" for a random uniform sampling over a sphere of radius radius. Also available "maximim" for a maximim LHS.

<code>radius</code>	the size of the radius of the sphere for uniform DoE or the semi length of the interval on each dimension for maximin LHS
<code>X</code>	(optional) a first Design of Experiment to be used instead of building a new DoE
<code>y</code>	the value of <code>lsf</code> on the <code>X</code>
<code>covariance</code>	(optional) to give a covariance kernel for the <code>km</code> object.
<code>learn_each_train</code>	a integer: after this limit the covariance parameters are not learnt any more and model is just updated with the new datapoints.
<code>km.param</code>	(optional) list of parameters to be passed to <code>DiceKriging::km</code> .
<code>burnin</code>	a burnin parameter for Markov Chain drawing of the metamodel based Poisson process (this does not change the number of calls to <code>lsf</code>).
<code>fast</code>	in current implementation it appears that the call to the metamodel is faster when doing batch computation. This parameter lets do the Markov chain the other way around: instead of first selecting a starting point and then applying burnin times the transition kernel, it creates a working population by apply the kernel to all the particles and then makes some moves with the generated discretised distribution.
<code>sur</code>	a list containing any parameters to be passed to <code>estimateSUR</code> . Default is <code>sur\$integrated=TRUE</code> and <code>sur\$r=1</code> for a one step ahead integrated SUR criterion.
<code>lower.tail</code>	as for <code>pxxxx</code> functions, TRUE for estimating $P(\text{lsf}(X) < q)$, FALSE for $P(\text{lsf}(X) > q)$.
<code>save.dir</code>	(optional) a directory to save the <code>X</code> and <code>y</code> at each iteration.
<code>plot</code>	to plot the DoE and the updated model.
<code>plot.lsf</code>	to plot the contour of the true <code>lsf</code> . Note that this requires its evaluation on a grid and should be used only on toy examples.
<code>plot.lab</code>	the labels of the axis for the plot.
<code>chi2</code>	for a chi2 test on the number of events.
<code>verbose</code>	controls the level of outputs of the algorithm.
<code>breaks</code>	optional, for the final histogram if <code>chi2 == TRUE</code> .

Details

The Bayesian Moving Particles algorithm uses the point process framework for rare event to iteratively estimate the conditional expectation of the (random) limit-state function, to quantify the quality of the learning and to propose a new point to be added to the model with a SUR criterion.

Value

An object of class `list` containing the outputs described below:

<code>alpha</code>	the estimated conditional expectation of the probability.
<code>alpha.seq</code>	the sequence of estimated alpha during the refinement step.
<code>cv2</code>	an estimate of the squared coefficient of variation of alpha.

cv.seq	the sequence of the estimated coefficients of variations.
h	the sequence of the estimated upper bound of the conditional variance divided by estimated alpha.
I	the sequence of the estimated integrated h.
sur_min	a list containing the the sequence of corresponding thresholds and -log probability of the sample minimising the SUR criterion.
sur_stat	a list containing at each iterations number of points tried for the SUR criterion as well as the computational spent.
q	the reference quantile for the probability estimate.
ecdf	the empirical cdf, i.e. the estimation of the function $q \rightarrow E(\alpha(q))$.
L_max	the farthest state reached by the random process. Validity range for the ecdf is then $(-\text{Inf}, L_max]$ or $[L_max, \text{Inf})$.
PPP	the last Poisson process generated with N. final particles.
meta_fun	the metamodel approximation of the lsf. A call output is a list containing the value and the standard deviation.
model	the final metamodel. An S4 object from DiceKriging . Note that the algorithm enforces the problem to be the estimation of $P[\text{lsf}(X) > q]$ and so using 'predict' with this object will return inverse values if <code>lower.tail==TRUE</code> ; in this scope prefer using directly meta_fun which handles this possible issue.
model.first	the first metamodel with the intial DoE.
alpha_int	a 95% confidence intervale on the estimate of alpha.
moves	a vector containing the number of moves for each one of the N. batch particles.
chi2	the output of the chisq.test function.

Note

Probleme should be defined in the standard space. Transformations can be made using UtoX and XtoU functions.

## Not run: p <- BMP(dimension = 2, lsf = cantilever, q = 1/325, N = 100, N.iter = 30, plot = TRUE)
```

cantilever

A function calculating the deviation of a cantilever beam.

Description

The limit-state function is defined in the standard space and isoprobabilistic transformation is used internally.

Usage

```
cantilever
```

Format

The function can handle a vector or a matrix with column vectors.

References

Gayton, N. and Bourinet, J.-M. and Lemaire, M.:
CD2RS: a new statistical approach to the response surface method for reliability analysis.
Structural Safety 25 99-121, 2003.

ComputeDistributionParameter

Compute internal parameters and moments for univariate distribution functions

Description

Compute the internal parameters needed in the definition of several distribution functions when unknown

Usage

```
ComputeDistributionParameter(margin)
```

Arguments

margin A list containing the definition of the marginal distribution function

Value

margin The updated list

Author(s)

gilles DEFAUX, <gilles.defaux@cea.fr>

Examples

```
distX1 <- list(type='Lnorm', MEAN=120.0, STD=12.0, P1=NULL, P2=NULL, NAME='X1')
distX1 <- ComputeDistributionParameter(distX1)
print(distX1)
```

estimateSUR

EstimateSUR

Description

A function for estimating a SUR criterion with a realisation of a PPP

Usage

```
estimateSUR(
  PPP,
  xi_PPP_X,
  integrated = TRUE,
  N_ppp,
  method = "discrete",
  SUR_pop,
  r = N.batch,
  optimcontrol = list(pop.size = 50 * d, max.generations = 10 * d),
  approx.pnorm,
  J = 0,
  N.batch = foreach::getDoParWorkers(),
  verbose = 0,
  ...
)
```

Arguments

PPP	the Poisson point process generated to get alpha.
xi_PPP_X	the output of xi(cbind(PPP\$X, PPP\$final_X)).
integrated	boolean to specify if SUR criterion is standard or integrated.
N_ppp	the number of Poisson processes used for the SUR criterion estimation.
method	either "genoud" for an optimisation using the package rgenoud or "discrete" for a discrete search over SUR_pop.
SUR_pop	if optimcontrol\$method=="discrete", SUR_pop is the population onto which minimizer is sought. Should be a matrix d x n.
r	number of points to be added to the DoE.
optimcontrol	a list of control parameters for the optimisation of the SUR criterion using the rgenoud package.
approx.pnorm	(optional) an approximation of base pnorm function running faster.
J	the center of an interval of size 8 for pnorm approximation.
N.batch	Number of batches for parallel computation.
verbose	to control the print level of the algorithm
...	further arguments to be passed to fSUR.

Value

a list containing the points minimising the criterion

 FORM

First-order reliability method

Description

The First-Order Reliability Method computes an estimation of the failure probability by approximating the limit-state function at the Most Probable Failure Point with a hyperplane.

Usage

```
FORM(
  dimension,
  lsf,
  u.dep = rep(0, dimension),
  N.calls = 100,
  eps = 1e-07,
  Method = "HLRF",
  IS = FALSE,
  IS.ratio = 0.5,
  plot = FALSE,
  plot.lsf = FALSE,
  plot.lab = c("x_1", "x_2")
)
```

Arguments

dimension	the dimension of the input space.
lsf	the limit-state function.
u.dep	the starting point for the MPFP search.
N.calls	the total number of calls for the whole algorithm.
eps	stopping criterion: distance of two points between two iterations.
Method	choice of the method to search the design point: "AR" for Abdo-Rackwitz and "HLRF" for Hasofer-Lindt-Rackwitz-Fiessler.
IS	"TRUE" for using importance Sampling method with an standard Gaussian importance density centred at the MPFP.
IS.ratio	ratio of N.calls for the search of the design point by FORM. Default = 0.5. 1-IS.ratio = the remaining ratio to be used for importance sampling.
plot	to plot the generated samples.
plot.lsf	a boolean indicating if the lsf should be added to the plot. This requires the evaluation of the lsf over a grid and consequently should be used only for illustration purposes.
plot.lab	the x and y labels for the plot.

FORMv0 *FORM method (old version)*

Description

Calculate failure probability by FORM method and important sampling.

Usage

```
FORMv0(f, u.dep, inputDist, N.calls, eps = 1e-7,
       Method = "HLRF", IS = FALSE, q = 0.5, copula = "unif")
```

Arguments

f	A failure fonction
u.dep	A vector, starting point to the research of the design point
inputDist	A list which contains the name of the input distribution and their parameters. For the input "i", inputDistribution[[i]] = list("name_law",c(parameters1,...., parametersN))
N.calls	Number of calls to f allowed
eps	Stop criterion : distance of two points between two iterations
Method	Choice of the method to research the design point: "AR" for Abdo-Rackwitz and "HLRF" for Hasofer-Lindt-Rackwitz-Fiessler
IS	"TRUE" for using importance Sampling method (applied after FORM which provides the importance density). Default = "FALSE".
q	Ratio of N.calls for the research of the design point by FORM. Default = 0.5. 1-q = the remaining ratio to use importance sampling.
copula	Choice of the copula. Default = "unif" (uniform copula)

Details

This function estimate the probability that the output of the failure function is negative using FORM algorithm. The importance sampling procedure estimate a probability using a Gaussian distribution centered in the design point with a covariance matrix equal to the identity.

Value

pf	Failure probability
beta	Reliability index (beta)
compt.f	Number of calls to f
design.point	Coordinates of the design point
fact.imp	Importance factors
variance	Standard error of the probability estimator (if IS = TRUE)

conf	Confidence interval of the estimator at 0.95 (if IS = TRUE)
x	A data frame containing the input design of experiments
y	A vector of model responses (corresponding to x)
dy	A data frame of model response derivatives (wrt each input and corresponding to x); for the IS sample, the derivatives are not computed

generateK

Generate Standard Gaussian samples with a Gaussian transition kernel

Description

Generate Standard Gaussian samples with a Gaussian transition kernel

Usage

```
generateK(X, N = 100, thinning = 4, sigma = 1, lsf, burnin = 20)
```

Arguments

X	the seeds for the Markov Chain. There are as many MC drawn as given seeds
N	the number of desired samples"
thinning	the proportion of kept samples, ie. 1 each thinning draw.
sigma	the exploration parameter for the transition kernel
lsf	a boolean limit-state function for definig a subdomain of the input space.
burnin	the burnin parameter, ie. the number of discarded samples before keeping one.

Details

This function generates standard Gaussian samples with a Markov Chain using a suitable transition kernel

Value

A matrix X with the number of desired samples

Author(s)

Clement WALTER <clementwalter@icloud.com>

Examples

```
# Get a seed in dimension 2
X <- matrix(rnorm(2), nrow = 2)
X <- generateK(X, N = 1000)

library(ggplot2)
ggplot(as.data.frame(t(X)), aes(x_1,x_2)) + geom_point()

# One can also specify a limit-state function
lsf <- function(X){
  sqrt(colSums(X^2)) > 2
}
X <- matrix(c(2, 2), nrow = 2)
X <- generateK(X, N = 1000, lsf = lsf)

ggplot(as.data.frame(t(X)), aes(x_1,x_2)) + geom_point()
```

 IRW

Increasing Random Walk

Description

Simulate the increasing random walk associated with a real-valued continuous random variable.

Usage

```
IRW(
  dimension,
  lsf,
  N = 10,
  q = Inf,
  Nevent = Inf,
  X,
  y = lsf(X),
  K,
  burnin = 20,
  sigma = 0.3,
  last.return = TRUE,
  use.potential = TRUE,
  plot = FALSE,
  plot.lsf = FALSE,
  print_plot = FALSE,
  output_dir = NULL,
  plot.lab = c("x_1", "x_2")
)
```

Arguments

dimension	dimension of the input space.
lsf	limit state function.
N	number of particles.
q	level until which the random walk is to be generated.
Nevent	the number of desired events.
X	to start with some given particles.
y	value of the lsf on X.
K	kernel transition for conditional generations.
burnin	burnin parameter.
sigma	radius parameter for K.
last.return	if the last event should be returned.
use.potential	to use a 'potential' matrix to select starting point not directly related to the sample to be moved with the MH algorithm.

<code>plot</code>	if TRUE, the algorithm plots the evolution of the particles. This requires to evaluate the <code>lsf</code> on a grid and is only for visual purpose.
<code>plot.lsf</code>	a boolean indicating if the <code>lsf</code> should be added to the plot. This requires the evaluation of the <code>lsf</code> over a grid and consequently should be used only for illustration purposes.
<code>print_plot</code>	if TRUE, print the updated plot after each iteration. This might be slow; use with a small <code>N</code> . Otherwise it only prints the final plot.
<code>output_dir</code>	if plots are to be saved in pdf in a given directory. This will be pasted with <code>'_IRW.pdf'</code> . Together with <code>print_plot==TRUE</code> this will produce a pdf with a plot at each iteration, enabling 'video' reconstitution of the algorithm.
<code>plot.lab</code>	the x and y labels for the plot

Details

This function lets generate the increasing random walk associated with a continuous real-valued random variable of the form $Y = \text{lsf}(X)$ where X is vectorial random variable.

This random walk can be associated with a Poisson process with parameter `N` and hence the number of iterations before a given threshold `q` is directly related to $P[\text{lsf}(X) > q]$. It is the core tool of algorithms such as nested sampling, Last Particle Algorithm or Tootsie Pop Algorithm.

Basically for `N = 1`, it generates a sample $Y = \text{lsf}(X)$ and iteratively regenerates greater than the found value: $Y_{n+1} \sim \mu^Y(\cdot | Y > Y_n)$. This regeneration step is done with a Metropolis-Hastings algorithm and that is why it is useful to consider generating several chains all together (`N > 1`).

The algorithm stops when it has simulated the required number of events `Nevent` or when it has reached the sought threshold `q`.

Value

An object of class `list` containing the following data:

<code>L</code>	the events of the random walk.
<code>M</code>	the total number of iterations.
<code>Ncall</code>	the total number of calls to the <code>lsf</code> .
<code>X</code>	a matrix containing the final particles.
<code>y</code>	the value of <code>lsf</code> on <code>X</code> .
<code>q</code>	the threshold considered when generating the random walk.
<code>Nevent</code>	the target number of events when generating the random walk.
<code>Nwmoves</code>	the number of rejected transitions, ie when the proposed point was not strictly greater/lower than the current state.
<code>acceptance</code>	a vector containing the acceptance rate for each use of the MH algorithm.

Note

Problem is supposed to be defined in the standard space. If not, use [UtoX](#) to do so. Furthermore, each time a set of vector is defined as a matrix, 'nrow' = dimension and 'ncol' = number of vector to be consistent with `as.matrix` transformation of a vector.

Algorithm calls `lsf(X)` (where X is a matrix as defined previously) and expects a vector in return. This allows the user to optimise the computation of a batch of points, either by vectorial computation, or by the use of external codes (optimised C or C++ codes for example) and/or parallel computation; see examples in [MonteCarlo](#).

```

kiureghian	<i>A limit-state-function defined by Der Kiureghian</i>
------------	---

Description

The limit-state function is defined by:

$$f(x) = b - x_2 - \kappa * (x_1 - e)^2$$

with $b = 5$, $\kappa = 0.5$ and $e = 0.1$.

Usage

```
kiureghian
```

Format

The function can handle a vector or matrix with column vectors.

LSVM	<i>Linear Support Vector Machine under monotonicity constraints</i>
------	---

Description

Produce a globally increasing binary classifier built from linear monotonic SVM

Usage

```
LSVM(x, A.model.lsvm, convexity)
```

Arguments

x	a set of points where the class must be estimated.
A.model.lsvm	a matrix containing the parameters of all hyperplanes.
convexity	Either -1 if the set of data associated to the label "-1" is convex or +1 otherwise.

Details

LSVM is a monotonic binary classifier built from linear SVM under the constraint that one of the two classes of data is convex.

Value

An object of class integer representing the class of x

res A vector of -1 or +1.

MetaIS	<i>Metamodel based Importance Sampling</i>
--------	--

Description

Estimate failure probability by MetaIS method.

Usage

```
MetaIS(  
  dimension,  
  lsf,  
  N = 5e+05,  
  N_alpha = 100,  
  N_DOE = 10 * dimension,  
  N1 = N_DOE * 30,  
  Ru = 8,  
  Nmin = 30,  
  Nmax = 200,  
  Ncall_max = 1000,  
  precision = 0.05,  
  N_seeds = 2 * dimension,  
  Niter_seed = Inf,  
  N_alphaL00 = 5000,  
  K_alphaL00 = 1,  
  alpha_int = c(0.1, 10),  
  k_margin = 1.96,  
  lower.tail = TRUE,  
  X = NULL,  
  y = NULL,  
  failure = 0,  
  meta_model = NULL,  
  kernel = "matern5_2",  
  learn_each_train = TRUE,  
  limit_fun_MH = NULL,  
  failure_MH = 0,  
  sampling_strategy = "MH",  
  seeds = NULL,  
  seeds_eval = limit_fun_MH(seeds),  
  burnin = 20,  
  compute.PPP = FALSE,  
  plot = FALSE,  
  limited_plot = FALSE,  
  add = FALSE,  
  output_dir = NULL,  
  verbose = 0  
)
```

Arguments

dimension	of the input space
lsf	the failure defining the failure/safety domain
N	size of the Monte-Carlo population for P_epsilon estimate
N_alpha	initial size of the Monte-Carlo population for alpha estimate
N_DOE	size of the initial DOE got by clustering of the N1 samples
N1	size of the initial uniform population sampled in a hypersphere of radius Ru
Ru	radius of the hypersphere for the initial sampling
Nmin	minimum number of call for the construction step
Nmax	maximum number of call for the construction step
Ncall_max	maximum number of call for the whole algorithm
precision	desired maximal value of cov
N_seeds	number of seeds for MH algorithm while generating into the margin (according to MP^*_{gauss})
Niter_seed	maximum number of iteration for the research of a seed for alphaLOO refinement sampling
N_alphaLOO	number of points to sample at each refinement step
K_alphaLOO	number of clusters at each refinement step
alpha_int	range for alpha to stop construction step
k_margin	margin width; default value means that points are classified with more than 97,5%
lower.tail	specify if one wants to estimate $P[\text{lsf}(X) < \text{failure}]$ or $P[\text{lsf}(X) > \text{failure}]$.
X	Coordinates of already known points
y	Value of the LSF on these points
failure	Failure threshold
meta_model	Provide here a kriging metamodel from km if wanted
kernel	Specify the kernel to use for km
learn_each_train	Specify if kernel parameters are re-estimated at each train
limit_fun_MH	Define an area of exclusion with a limit function
failure_MH	Threshold for the limit_MH function
sampling_strategy	Either MH for Metropolis-Hastings or AR for accept-reject
seeds	If some points are already known to be in the appropriate subdomain
seeds_eval	Value of the metamodel on these points
burnin	Burnin parameter for MH
compute.PPP	to simulate a Poisson process at each iteration to estimate the conditional expectation and the SUR criteria based on the conditional variance: h (average probability of misclassification at level failure) and I (integral of h over the whole interval [failure, infity))

plot	Set to TRUE for a full plot, ie refresh at each iteration
limited_plot	Set to TRUE for a final plot with final DOE, metamodel and LSF
add	If plots are to be added to a current device
output_dir	If plots are to be saved in jpeg in a given directory
verbose	Either 0 for almost no output, or 1 for medium size or 2 for all outputs

Details

MetaIS is an Important Sampling based probability estimator. It makes use of a kriging surrogate to approximate the optimal density function, replacing the indicatrice by its kriging pendant, the probability of being in the failure domain. In this context, the normalizing constant of this quasi-optimal PDF is called the ‘augmented failure probability’ and the modified probability ‘alpha’.

After a first uniform Design of Experiments, MetaIS uses an alpha Leave-One-Out criterion combined with a margin sampling strategy to refine a kriging-based metamodel. Samples are generated according to the weighted margin probability with Metropolis-Hastings algorithm and some are selected by clustering; the N_{seeds} are got from an accept-reject strategy on a standard population.

Once criterion is reached or maximum number of call done, the augmented failure probability is estimated with a crude Monte-Carlo. Then, a new population is generated according to the quasi-optimal instrumental PDF; burnin and thinning are used here and alpha is evaluated. While the coefficient of variation of alpha estimate is greater than a given threshold and some computation spots still available (defined by $N_{\text{call_max}}$) the estimate is refined with extra calculus.

The final probability is the product of p_{epsilon} and alpha, and final squared coefficient of variation is the sum of p_{epsilon} and alpha one’s.

Value

An object of class `list` containing the failure probability and some more outputs as described below:

<code>p</code>	The estimated failure probability.
<code>cov</code>	The coefficient of variation of the Monte-Carlo probability estimate.
<code>Ncall</code>	The total number of calls to the <code>lsf</code> .
<code>X</code>	The final learning database, ie. all points where <code>lsf</code> has been calculated.
<code>y</code>	The value of the <code>lsf</code> on the learning database.
<code>meta_fun</code>	The metamodel approximation of the <code>lsf</code> . A call output is a list containing the value and the standard deviation.
<code>meta_model</code>	The final metamodel. An S4 object from DiceKriging . Note that the algorithm enforces the problem to be the estimation of $P[\text{lsf}(X) < \text{failure}]$ and so using ‘predict’ with this object will return inverse values if <code>lower.tail==FALSE</code> ; in this scope prefer using directly <code>meta_fun</code> which handle this possible issue.
<code>points</code>	Points in the failure domain according to the metamodel.
<code>h</code>	the sequence of the estimated relative SUR criteria.
<code>I</code>	the sequence of the estimated integrated SUR criteria.

Note

Problem is supposed to be defined in the standard space. If not, use [UtoX](#) to do so. Furthermore, each time a set of vector is defined as a matrix, 'nrow' = dimension and 'ncol' = number of vector to be consistent with `as.matrix` transformation of a vector.

Algorithm calls `lsf(X)` (where X is a matrix as defined previously) and expects a vector in return. This allows the user to optimise the computation of a batch of points, either by vectorial computation, or by the use of external codes (optimised C or C++ codes for example) and/or parallel computation; see examples in [MonteCarlo](#).

```

MetropolisHastings *The modified Metropolis-Hastings algorithm*

Description

The function implements the specific modified Metropolis-Hastings algorithm as described first by Au & Beck and including another scaling parameter for an extended search in initial steps of the SMART algorithm.

Usage

```

MetropolisHastings(
  x0,
  eval_x0 = -1,

```

```

chain_length,
modified = TRUE,
sigma = 0.3,
proposal = "Uniform",
lambda = 1,
limit_fun = function(x) {      -1 },
burnin = 20,
thinning = 4
)

```

Arguments

<code>x0</code>	the starting point of the Markov chain
<code>eval_x0</code>	the value of the limit-state function on <code>x0</code>
<code>chain_length</code>	the length of the Markov chain. At the end the chain will be <code>chain_length + 1</code> long
<code>modified</code>	a boolean to use either the original Metropolis-Hastings transition kernel or the coordinate-wise one
<code>sigma</code>	a radius parameter for the Gaussian or Uniform proposal
<code>proposal</code>	either "Uniform" for a Uniform random variable in an interval <code>[-sigma, sigma]</code> or "Gaussian" for a centred Gaussian random variable with standard deviation <code>sigma</code>
<code>lambda</code>	the coefficient to increase the likelihood ratio
<code>limit_fun</code>	the limite-state function delimiting the domain to sample in
<code>burnin</code>	a burnin parameter, ie a number of initial discards samples
<code>thinning</code>	a thinning parameter, ie that one sample over <code>thinning</code> samples is kept along the chain

Details

The modified Metropolis-Hastings algorithm is supposed to be used in the Gaussian standard space. Instead of using a proposed point for the multidimensional Gaussian random variable, it applies a Metropolis step to each coordinate. Then it generates the multivariate candidate by checking if it lies in the right domain.

This version proposed by Bourinet et al. includes an scaling parameter `lambda`. This parameter is multiplied with the likelihood ratio in order to increase the chance of accepting the candidate. While it biases the output distribution of the Markov chain, the authors of SMART suggest its use (`lambda > 1`) for the exploration phase. Note such a value disable to possiblity to use the output population for Monte Carlo estimation.

Value

A list containing the following entries:

<code>points</code>	the generated Markov chain
<code>eval</code>	the value of the limit-state function on the generated samples

acceptation	the acceptance rate
Ncall	the total number of call to the limit-state function
samples	all the generated samples
eval_samples	the evaluation of the limit-state function on the samples samples

modelLSVM

Estimation of the parameters of the LSVM

Description

Produce a matrix containing the parameters of a set of hyperplanes separating the two classes of data

Usage

```
modelLSVM(X, Y, convexity)
```

Arguments

X	a matrix containing the data sets
Y	a vector containing -1 or +1 that represents the class of each elements of X.
convexity	Either -1 if the set of data associated to the label "-1" is convex or +1 otherwise.

Details

modelLSVM evaluate the classifier on a set of points.

Value

An object of class `matrix` containing the parameters of a set of hyperplanes

`res` A matrix where each lines contains the parameters of a hyperplane.

```

 ModifCorrMatrix

Modification of a correlation matrix to use in UtoX

Description

ModifCorrMatrix modifies a correlation matrix originally defined using SPEARMAN correlation coefficients to the correlation matrix to be used in the NATAF transformation performed in UtoX.

Usage

```
ModifCorrMatrix(Rs)
```

Arguments

Rs Original correlation matrix defined using SPEARMAN correlation coefficient :

$$R_s = [\rho_{ij}^s]$$

Value

R0 Modified correlation matrix

Note

The NATAF distribution is reviewed from the (normal) copula viewpoint as a particular and convenient means to describe a joint probabilistic model assuming that the normal copula fits to the description of the input X. The normal copula is defined by a symmetric positive definite matrix R0. Even though the off-diagonal terms in this matrix are comprised in]-1; 1[and its diagonal terms are equal to 1, it shall not be confused with the more usual correlation matrix. Lebrun and Dutfoy point out that the SPEARMAN (or rank) correlation coefficient is better suited to parametrize a copula because it leads to a simpler closed-form expression for ρ_{ij} .

MonotonicQuantileEstimation

Quantile estimation under monotonicity constraints

Description

Estimate a quantile with the constraints that the function is monotone

Usage

```
MonotonicQuantileEstimation(f,
                             inputDimension,
                             inputDistribution,
                             dir.monot,
                             N.calls,
                             p,
                             method,
                             X.input = NULL,
                             Y.input = NULL)
```

Arguments

f	a failure fonction
inputDimension	dimension of the inputs
inputDistribution	a list of length 'inputDimension' which contains the name of the input distribution and their parameters. For the input "i", inputDistribution[[i]] = list("name_law",c(parameters1,...,parametersN))
dir.monot	vector of size inputDimension which represents the monotonicity of the failure function. dir.monot[i] = -1 (resp. 1) if the failure function f is decreasing (resp. increasing) according with direction i.
N.calls	Number of calls to f allowed
method	there are four methods available. "MonteCarloWB" provides the empirical quantile estimator, "MonteCarloWB" provides the empirical quantile estimator as well as two bounds for the searched quantile, "Bounds" provides two bounds for a quantile from a set of points and "MonteCarloIS" provides an estimate of a quantile based on a sequential framework of simulation.
p	the probability associated to the quantile
X.input	a set of points
Y.input	value of f on X.input

Details

MonotonicQuantileEstimation provides many methods to estimate a quantile under monotonicity constraints.

Value

An object of class list containing the quantile as well as:

qm	A lower bound of the quantile.
qM	A upperer bound of the quantile.
q.hat	An estimate of the quantile.
Um	A lower bounds of the probability obtained from the desing of experiments.

UM	An upper bounds of the probability obtained from the desing of experiments.
XX	Design of experiments
YY	Values of on XX

Note

Inputs X.input and Y.input are useful only for method = "Bounds"

## End(Not run)
```

MonteCarlo

Crude Monte Carlo method

Description

Estimate a failure probability using a crude Monte Carlo method.

Usage

```
MonteCarlo(
  dimension,
  lsf,
  N_max = 5e+05,
  N_batch = foreach::getDoParWorkers(),
  q = 0,
  lower.tail = TRUE,
  precision = 0.05,
  plot = FALSE,
  output_dir = NULL,
  save.X = TRUE,
  verbose = 0
)
```

Arguments

<code>dimension</code>	the dimension of the input space.
<code>lsf</code>	the function defining safety/failure domain.
<code>N_max</code>	maximum number of calls to the <code>lsf</code> .
<code>N_batch</code>	number of points evaluated at each iteration.
<code>q</code>	the quantile.
<code>lower.tail</code>	as for <code>pxxxx</code> functions, TRUE for estimating $P(\text{lsf}(X) < q)$, FALSE for $P(\text{lsf}(X) > q)$.
<code>precision</code>	a targeted maximum value for the coefficient of variation.
<code>plot</code>	to plot the contour of the <code>lsf</code> as well as the generated samples.
<code>output_dir</code>	to save a copy of the plot in a pdf. This name will be pasted with " <code>_Monte_Carlo_brut.pdf</code> ".
<code>save.X</code>	to save all the samples generated as a matrix. Can be set to FALSE to reduce output size.
<code>verbose</code>	to control the level of outputs in the console; either 0 or 1 or 2 for almost no outputs to a high level output.

Details

This implementation of the crude Monte Carlo method works with evaluating batches of points sequentially until a given precision is reached on the final estimator

Value

An object of class `list` containing the failure probability and some more outputs as described below:

<code>p</code>	the estimated probability.
<code>ecdf</code>	the empirical cdf got with the generated samples.
<code>cov</code>	the coefficient of variation of the Monte Carlo estimator.
<code>Ncall</code>	the total number of calls to the <code>lsf</code> , ie the total number of generated samples.
<code>X</code>	the generated samples.
<code>Y</code>	the value <code>lsf(X)</code> .

Note

Problem is supposed to be defined in the standard space. If not, use `UtoX` to do so. Furthermore, each time a set of vector is defined as a matrix, 'nrow' = dimension and 'ncol' = number of vector to be consistent with `as.matrix` transformation of a vector.

Algorithm calls `lsf(X)` (where `X` is a matrix as defined previously) and expects a vector in return. This allows the user to optimise the computation of a batch of points, either by vectorial computation, or by the use of external codes (optimised C or C++ codes for example) and/or parallel computation.

MP

Moving Particles

Description

This function runs the Moving Particles algorithm for estimating extreme probability and quantile.

Usage

MP(

```

dimension,
lsf,
N = 100,
N.batch = foreach::getDoParWorkers(),
p,
q,
lower.tail = TRUE,
Niter_1fold,
alpha = 0.05,
compute_confidence = FALSE,
verbose = 0,
chi2 = FALSE,
breaks = N.batch/5,
...
)

```

Arguments

<code>dimension</code>	the dimension of the input space.
<code>lsf</code>	the function defining the RV of interest $Y = \text{lsf}(X)$.
<code>N</code>	the total number of particles,
<code>N.batch</code>	the number of parallel batches for the algorithm. Each batch will then have $N/N.\text{batch}$ particles. Typically this could be <code>detectCores()</code> or some other machine-derived parameters. Note that $N/N.\text{batch}$ has to be an integer.
<code>p</code>	a given probability to estimate the corresponding quantile (as in <code>qxxxx</code> functions).
<code>q</code>	a given quantile to estimate the corresponding probability (as in <code>pxxxx</code> functions).
<code>lower.tail</code>	as for <code>pxxxx</code> functions, TRUE for estimating $P(\text{lsf}(X) < q)$, FALSE for $P(\text{lsf}(X) > q)$.
<code>Niter_1fold</code>	a function = <code>fun(N)</code> giving the deterministic number of iterations for the first pass.
<code>alpha</code>	when using default <code>Niter_1fold</code> function, this is the risk not to have simulated enough samples to produce a quantile estimator.
<code>compute_confidence</code>	if TRUE, the algorithm runs a little bit longer to produces a 95% interval on the quantile estimator.
<code>verbose</code>	to control level of print (either 0, or 1, or 2).
<code>chi2</code>	for a <code>chi2</code> test on the number of events.
<code>breaks</code>	for the final histogram is <code>chi2 == TRUE</code> .
<code>...</code>	further arguments past to IRW .

Details

MP is a wrap up of [IRW](#) for probability and quantile estimation. By construction, the several calls to [IRW](#) are parallel (**foreach**) and so is the algorithm. Especially, with `N.batch=1`, this is the Last Particle Algorithm, which is a specific version of [SubsetSimulation](#) with $p_0 = 1-1/N$. However, note that this algorithm not only gives a quantile or a probability estimate but also an estimate of the whole cdf until the given threshold q .

The probability estimator only requires to generate several random walks as it is the estimation of the parameter of a Poisson random variable. The quantile estimator is a little bit more complicated and requires a 2-passes algorithm. It is thus not exactly fully parallel as cluster/cores have to communicate after the first pass. During the first pass, particles are moved a given number of times, during the second pass particles are moved until the farthest event reach during the first pass. Hence, the random process is completely simulated until this given state.

For an easy user experiment, all the parameters are defined by default with the optimised values as described in the reference paper (see References below) and a typical use will only specify `N` and `N.batch`.

Value

An object of class `list` containing the outputs described below:

<code>p</code>	the estimated probability or the reference for the quantile estimate.
<code>q</code>	the estimated quantile or the reference for the probability estimate.
<code>cv</code>	the coefficient of variation of the probability estimator.
<code>ecdf</code>	the empirical cdf.
<code>L</code>	the states of the random walk.
<code>L_max</code>	the farthest state reached by the random process. Validity range for the ecdf is then $(-\text{Inf}, L_max]$ or $[L_max, \text{Inf})$.
<code>times</code>	the <i>times</i> of the random process.
<code>Ncall</code>	the total number of calls to the <code>lsf</code> .
<code>X</code>	the <code>N</code> particles in their final state.
<code>y</code>	the value of the <code>lsf(X)</code> .
<code>moves</code>	a vector containing the number of moves for each batch.
<code>p_int</code>	a 95% confidence interval on the probability estimate.
<code>cov</code>	the coefficient of variation of the estimator
<code>q_int</code>	a 95% confidence interval on the quantile estimate.
<code>chi2</code>	the output of the <code>chisq.test</code> function.

Note

The alpha parameter is set to 0.05 by default. Indeed it should not be set too small as it is defined approximating the Poisson distribution with the Gaussian one. However if no estimate is produced then the algorithm can be restarted for the few missing events. In any cases, setting `N.iter_1fold = -N/N.batch*log(p)` gives 100% chances to produce a quantile estimator.

```

 MRM

MRM method

Description

Estimate a failure probability by MRM method.

Usage

```
MRM(f, inputDimension, inputDistribution, dir.monot, N.calls, Method, silent = FALSE)
```

Arguments

<code>f</code>	a failure fonction
<code>inputDimension</code>	dimension of the inputs
<code>inputDistribution</code>	a list of length 'inputDimension' which contains the name of the input distribution and their parameters. For the input "i", <code>inputDistribution[[i]] = list("name_law",c(parameters1,..., parametersN))</code>
<code>dir.monot</code>	vector of size <code>inputDimension</code> which represents the monotonicity of the failure function. <code>dir.monot[i] = -1</code> (resp. <code>1</code>) if the failure function <code>f</code> is decreasing (resp. increasing) according with direction <code>i</code> .
<code>N.calls</code>	Number of calls to <code>f</code> allowed
<code>Method</code>	there is two methods available. "MC" is an adaptation of the Monte Carlo method under constraints of monotony. "MRM" is based on a sequential sampling.
<code>silent</code>	if <code>silent = TRUE</code> , print curent number of call to <code>f</code> . Default: <code>FALSE</code> .

Details

These methods compute the probability that the output of the failure function is negative

Value

<code>Um</code>	Exact lower bounds of the failure probability
<code>UM</code>	Exact upper bounds of the failure probability
<code>MLE</code>	Maximum likelihood estimator of the failure probability
<code>IC.inf</code>	Lower bound of the confidence interval of the failure probability based on MLE
<code>IC.sup</code>	Upper bound of the confidence interval of the failure probability based on MLE
<code>CV.MLE</code>	Coefficient of variation of the MLE
<code>X</code>	design of experiments
<code>Y</code>	value of <code>f</code> on <code>X</code>
<code>N.tot</code>	Total number of simulation (only for "MC_monotone")

ok *Class of Ordinary Kriging*

Description

An implementation of Ordinary Kriging based upon a km-class object that should be faster than usual predict method.

Usage

```
ok(model, beta = NULL)
```

Arguments

model	a kriging model object from DiceKriging::km-class
beta	the trend of the model

Details

The Ordinary Kriging is a special case of kriging where the trend is supposed to be and unknown constant. Consequently some linear algebra operations can be reduced by knowing that the vector of parameter beta is indeed a real.

The ok class defines three functions: xi the kriging predictor, updateSd and updateSdfast two methods for updating the kriging variance when some points are virtually added to the model. These two last functions differ in their implementation: the first one allows for the user to specify which are the predicted points and which are the added points. The second one outputs a matrix where the kriging variances of all the points is updated when each one is iteratively added the the Design of Experiments.

The faster between looping updateSd and using updateSdfast is indeed problem dependent (depending on parallel computer, size of the data, etc.) and should be benchmark by the user.

Value

An object of S3 class 'ok' containing

Kinv	the inverse of the covariance matrix of the data
beta	the estimated coefficient of the trend
y_centred	the data centred according to the estimated trend
sigma_beta	the standard deviation of the estimation of beta
xi	the kriging predictor
updateSd	a function to calculate the updated kriging variance when Xnew points are added to the Design of Experiments
updateSdfast	a function to calculate the update kriging variance when the SUR criterion is minimised over a population which is also the one used to estimate it.

Examples

```
# Generate a dataset
X <- data.frame(x1 = rnorm(10), x2 = rnorm(10))
y <- cos(sqrt(rowSums(X^2)))

# Learn a model
krig <- DiceKriging::km(design=X, response=y)

# Create Ordinary Kriging object
OK <- ok(krig)

# Microbenchmark
# create a dataset
X = data.frame(x1 = rnorm(100), x2 = rnorm(100))
microbenchmark::microbenchmark(OK$xi(t(X)), predict(krig, X, type="UK"))

# Check identical results
X <- rnorm(2)
OK$xi(X)[c('mean', 'sd')]
predict(krig, data.frame(x1=X[1], x2=X[2]), type="UK")[c('mean', 'sd')]
```

oscillator_d6	<i>A limit-state-function defined with a non-linear oscillator in dimension 6.</i>
---------------	--

Description

The limit-state function is defined in the standard space and isoprobabilistic transformation is used internally.

Usage

```
oscillator_d6
```

Format

The function can handle a vector or a matrix with column vectors.

References

`plotLSVM`*plot of LSVM*

Description

Make a plot of the data and the LSVM classifier

Usage

```
plotLSVM(X,  
         Y,  
         A.model.lsvm,  
         hyperplanes = FALSE,  
         limit.state.estimate = TRUE,  
         convexity)
```

Arguments

<code>X</code>	a matrix containing the data sets
<code>Y</code>	a vector containing -1 or +1 that represents the class of each elements of <code>X</code> .
<code>A.model.lsvm</code>	a matrix containing the parameters of all hyperplanes.
<code>hyperplanes</code>	A boolean. If TRUE, plot the hyperplanes obtained.
<code>limit.state.estimate</code>	A boolean. If TRUE, plot the estimate of the limit state.
<code>convexity</code>	Either -1 if the set of data associated to the label "-1" is convex or +1 otherwise.

Details

`plotLSVM` makes a plot of the data as well as the estimate limit state and the hyperplanes involved in this construction.

Note

This function is useful only in dimension 2.

plotLSVM(X, Y, model.A, hyperplanes = FALSE, limit.state.estimate = TRUE, convexity = -1)

## End(Not run)
```

precomputeUpdateData *precomputeUpdateData*

Description

precomputeUpdateData

Usage

```
precomputeUpdateData(model, integration.points)
```

Arguments

model a object from km
integration.points the points onto which the updated variance will be computed

Value

A list containing the following elements

`Kinv.c.olddata` kriging weights for the integrations.points over `krig@X`
`Kinv.F` The matrix product of the inverse covariance and F the matrix of the trend functions at `model@X`
`first.member`

quantileWilks

Computing quantiles with the Wilks formula

Description

From the Wilks formula, compute a quantile (or a tolerance interval) with a given confidence level from a i.i.d. sample, or compute the minimal sample size to estimate a quantile (or a tolerance interval) with a given confidence level.

Usage

```
quantileWilks(alpha=0.95,beta=0.95,data=NULL,bilateral=FALSE)
```

Arguments

`alpha` level of the unilateral or bilateral quantile (default = 0.95)
`beta` level of the confidence interval on quantile value(s) (default = 0.95)
`data` the data sample (vector format) to compute the quantile(s); if `data=NULL` (by default), the function returns the minimal sample size to compute the required quantile
`bilateral` TRUE for bilateral quantile (default = unilateral = FALSE)

Value

4 output values if 'data' is specified; 1 output value (nmin) if 'data' is not specified

`lower` lower bound of the bilateral tolerance interval; if `bilateral=FALSE`, no value
`upper` upper bound of the tolerance interval (bilateral case) or quantile value (unilateral case)
`nmin` minimal size of the required i.i.d. sample for given alpha and beta: - bilateral case: tolerance interval will be composed with the min and max of the sample; - unilateral case: the quantile will correspond to max of the sample.
`ind` the index (unilateral case) or indices (bilateral case) of the quantiles in the ordered sample (increasing order)

print(N)
```

rackwitz

A limit-state-function defined by Rackwitz

Description

The function is defined in the standard space and internal normal-lognormal transformation is done. Its definition with iid lognormal random variables is:

$$d + a\sigma\sqrt{d} - \sum_{i=1}^d x_i$$

Default values are: $a = 1$, $\text{mean}=1$ and $\sigma = 0.2$.

Usage

```
rackwitz
```

Format

The function can handle a vector or a matrix with column vectors.

Reliability analysis: a review and some perspectives
Structural Safety, 23, 4, 365-395, 2001.

S2MART

*Subset by Support vector Margin Algorithm for Reliability esTimation***Description**

S2MART introduces a metamodeling step at each subset simulation threshold, making number of necessary samples lower and the probability estimation better according to subset simulation by itself.

Usage

```
S2MART(
  dimension,
  lsf,
  Nn = 100,
  alpha_quantile = 0.1,
  failure = 0,
  lower.tail = TRUE,
  ...,
  plot = FALSE,
  output_dir = NULL,
  verbose = 0
)
```

Arguments

<code>dimension</code>	the dimension of the input space
<code>lsf</code>	the function defining the failure domain. Failure is $lsf(X) < failure$
<code>Nn</code>	number of samples to evaluate the quantiles in the subset step
<code>alpha_quantile</code>	cutoff probability for the subsets
<code>failure</code>	the failure threshold
<code>lower.tail</code>	as for <code>pxxxx</code> functions, TRUE for estimating $P(lsf(X) < failure)$, FALSE for $P(lsf(X) > failure)$
<code>...</code>	All others parameters of the metamodel based algorithm
<code>plot</code>	to produce a plot of the failure and safety domain. Note that this requires a lot of calls to the <code>lsf</code> and is thus only for training purpose
<code>output_dir</code>	to save the plot into the given directory. This will be pasted with " <code>_S2MART.pdf</code> "
<code>verbose</code>	either 0 for almost no output, 1 for medium size output and 2 for all outputs

Details

S2MART algorithm is based on the idea that subset simulations conditional probabilities are estimated with a relatively poor precision as it requires calls to the expensive-to-evaluate limit state function and does not take benefit from its numerous calls to the limit state function in the Metropolis-Hastings algorithm. In this scope, the key concept is to reduce the subset simulation population to its

minimum and use it only to estimate crudely the next quantile. Then the use of a metamodel-based algorithm lets refine the border and calculate an accurate estimation of the conditional probability by the mean of a crude Monte-Carlo.

In this scope, a compromise has to be found between the two sources of calls to the limit state function as total number of calls = $(N_n + \text{number of calls to refine the metamodel}) \times (\text{number of subsets})$:

- N_n calls to find the next threshold value : the bigger N_n , the more accurate the 'decreasing speed' specified by the `alpha_quantile` value and so the smaller the number of subsets
- total number of calls to refine the metamodel at each threshold

Value

An object of class `list` containing the failure probability and some more outputs as described below:

<code>p</code>	The estimated failure probability.
<code>cov</code>	The coefficient of variation of the Monte-Carlo probability estimate.
<code>Ncall</code>	The total number of calls to the <code>lsf</code> .
<code>X</code>	The final learning database, ie. all points where <code>lsf</code> has been calculated.
<code>y</code>	The value of the <code>lsf</code> on the learning database.
<code>meta_model</code>	The final metamodel. An object from e1071 .

Note

Problem is supposed to be defined in the standard space. If not, use `UtoX` to do so. Furthermore, each time a set of vector is defined as a matrix, 'nrow' = dimension and 'ncol' = number of vector to be consistent with `as.matrix` transformation of a vector.

Algorithm calls `lsf(X)` (where `X` is a matrix as defined previously) and expects a vector in return. This allows the user to optimise the computation of a batch of points, either by vectorial computation, or by the use of external codes (optimised C or C++ codes for example) and/or parallel computation; see examples in [MonteCarlo](#).

  seeds = NULL,
  seeds_eval = NULL,
  burnin = 20,
  thinning = 4,
  plot = FALSE,
  limited_plot = FALSE,
  add = FALSE,
  output_dir = NULL,
  z_MH = NULL,
  z_lsf = NULL,
  verbose = 0
)
```

Arguments

dimension	the dimension of the input space
lsf	the limit-state function
N1	Number of samples for the (L)ocalisation step
N2	Number of samples for the (S)tabilisation step

N3	Number of samples for the (C)onvergence step
Nu	Size of the first Design of Experiments
lambda1	Relaxing parameter for MH algorithm at step L
lambda2	Relaxing parameter for MH algorithm at step S
lambda3	Relaxing parameter for MH algorithm at step C
tune_cost	Input for tuning cost paramter of the SVM
tune_gamma	Input for tuning gamma parameter of the SVM
clusterInMargin	Enforce selected clusterised points to be in margin
alpha_margin	a real value defining the margin. While 1 is the ‘real’ margin for a SVM, one can decide here to stretch it a bit.
k1	Rank of the first iteration of step S
k2	Rank of the first iteration of step C
k3	Rank of the last iteration of step C
X	Coordinates of already known points
y	Value of the LSF on these points
failure	Failure threshold
limit_fun_MH	Define an area of exclusion with a limit function
sampling_strategy	Either MH for Metropolis-Hastings or AR for accept-reject
seeds	If some points are already known to be in the subdomain defined by <code>limit_fun_MH</code>
seeds_eval	Value of the metamodel on these points
burnin	Burnin parameter for MH
thinning	Thinning parameter for MH
plot	Set to TRUE for a full plot, ie. refresh at each iteration
limited_plot	Set to TRUE for a final plot with final DOE, metamodel and LSF
add	If plots are to be added to the current device
output_dir	If plots are to be saved in jpeg in a given directory
z_MH	For plots, if the <code>limit_fun_MH</code> has already been evaluated on the grid
z_lsf	For plots, if LSF has already been evaluated on the grid
verbose	Either 0 for almost no output, 1 for medium size output and 2 for all outputs

Details

SMART is a reliability method proposed by J.-M. Bourinet et al. It makes use of a SVM-based metamodel to approximate the limit state function and calculates the failure probability with a crude Monte-Carlo method using the metamodel-based limit state function. As SVM is a classification method, it makes use of limit state function values to create two classes : greater and lower than the failure threshold. Then the border is taken as a surrogate of the limit state function.

Concerning the refinement strategy, it distinguishes 3 stages, known as Localisation, Stabilisation and Convergence stages. The first one is proposed to reduce the margin as much as possible, the second one focuses on switching points while the last one works on the final Monte-Carlo population and is designed to insure a strong margin; see F. Deheeger PhD thesis for more information.

Value

An object of class `list` containing the failure probability and some more outputs as described below:

<code>proba</code>	The estimated failure probability.
<code>cov</code>	The coefficient of variation of the Monte-Carlo probability estimate.
<code>Ncall</code>	The total number of calls to the <code>limit_state_function</code> .
<code>X</code>	The final learning database, ie. all points where <code>lsf</code> has been calculated.
<code>y</code>	The value of the <code>limit_state_function</code> on the learning database.
<code>meta_fun</code>	The metamodel approximation of the <code>limit_state_function</code> . A call output is a list containing the value and the standard deviation.
<code>meta_model</code>	The final metamodel.
<code>points</code>	Points in the failure domain according to the metamodel.
<code>meta_eval</code>	Evaluation of the metamodel on these points.
<code>z_meta</code>	If <code>plot==TRUE</code> , the evaluation of the metamodel on the plot grid.

Note

Problem is supposed to be defined in the standard space. If not, use `UtoX` to do so.

Furthermore, each time a set of vector is defined as a matrix, 'nrow' = dimension and 'ncol' = number of vector.

 SubsetSimulation *Subset Simulation Monte Carlo*

Description

Estimate a probability of failure with the Subset Simulation algorithm (also known as Multilevel Splitting or Sequential Monte Carlo for rare events).

Usage

```
SubsetSimulation(
  dimension,
  lsf,
  p_0 = 0.1,
  N = 10000,
  q = 0,
  lower.tail = TRUE,
  K,
  thinning = 20,
  save.all = FALSE,
  plot = FALSE,
  plot.level = 5,
  plot.lsf = TRUE,
  output_dir = NULL,
  plot.lab = c("x", "y"),
  verbose = 0
)
```

Arguments

<code>dimension</code>	the dimension of the input space.
<code>lsf</code>	the function defining failure/safety domain.
<code>p_0</code>	a cutoff probability for defining the subsets.
<code>N</code>	the number of samples per subset, ie the population size for the Monte Carlo estimation of each conditional probability.
<code>q</code>	the quantile defining the failure domain.
<code>lower.tail</code>	as for pxxxx functions, TRUE for estimating $P(\text{lsf}(X) < q)$, FALSE for $P(\text{lsf}(X) > q)$
<code>K</code>	a transition Kernel for Markov chain drawing in the regeneration step. $K(X)$ should propose a matrix of candidate sample (same dimension as X) on which lsf will be then evaluated and transition accepted or rejected. Default kernel is the one defined $K(X) = (X + \text{sigma} * W) / \sqrt{1 + \text{sigma}^2}$ with $W \sim N(0, 1)$.
<code>thinning</code>	a thinning parameter for the the regeneration step.
<code>save.all</code>	if TRUE, all the samples generated during the algorithms are saved and return at the end. Otherwise only the working population is kept at each iteration.

plot	to plot the generated samples.
plot.level	maximum number of expected levels for color consistency. If number of levels exceeds this value, the color scale will change according to ggplot2 default policy.
plot.lsf	a boolean indicating if the lsf should be added to the plot. This requires the evaluation of the lsf over a grid and consequently should be used only for illustration purposes.
output_dir	to save the plot into a pdf file. This variable will be pasted with "_Subset_Simulation.pdf"
plot.lab	the x and y labels for the plot
verbose	Either 0 for almost no output, 1 for medium size output and 2 for all outputs

Details

This algorithm uses the property of conditional probabilities on nested subsets to calculate a given probability defined by a limit state function.

It operates iteratively on ‘populations’ to estimate the quantile corresponding to a probability of p_0 . Then, it generates samples conditionally to this threshold, until found threshold be lower than 0.

Finally, the estimate is the product of the conditional probabilities.

Value

An object of class `list` containing the failure probability and some more outputs as described below:

p	the estimated failure probability.
cv	the estimated coefficient of variation of the estimate.
Ncall	the total number of calls to the lsf.
X	the working population.
Y	the value $lsf(X)$.
Xtot	if <code>save.list==TRUE</code> , all the Ncall samples generated by the algorithm.
Ytot	the value $lsf(Xtot)$.
sigma.hist	if default kernel is used, sigma is initialized with 0.3 and then further adaptively updated to have an average acceptance rate of 0.3

Note

Problem is supposed to be defined in the standard space. If not, use [UtoX](#) to do so. Furthermore, each time a set of vector is defined as a matrix, ‘nrow’ = dimension and ‘ncol’ = number of vector to be consistent with `as.matrix` transformation of a vector.

Algorithm calls $lsf(X)$ (where X is a matrix as defined previously) and expects a vector in return. This allows the user to optimise the computation of a batch of points, either by vectorial computation, or by the use of external codes (optimised C or C++ codes for example) and/or parallel computation; see examples in [MonteCarlo](#).

testConvexity	<i>Test the convexity of set of data</i>
---------------	--

Description

Provides the

Usage

```
testConvexity(X, Y)
```

Arguments

X a matrix containing the data sets
Y a vector containing -1 or +1 that represents the class of each elements of X.

Details

testConvexity test if one of the two data set is potentially convex.

Value

An object of class `list` containing the number of the class which is convex and the parameters of a set of hyperplanes separating the two classes

twodof

A limit-state-function defined with a two degrees of freedom damped oscillator

Description

The limit-state function is defined in the standard space and isoprobabilistic transformation is used internally.

Parameters mean_Fs and p can be specified and default are 27.5 and 3 respectively.

Usage

twodof

Format

The function can handle a vector or a matrix with column vectors.

updateLSVM	<i>Update LSVM classifier</i>
------------	-------------------------------

Description

Update the existing classifier LSVM with a new set of data.

Usage

```
updateLSVM(X.new,
           Y.new,
           X,
           Y,
           A.model.lsvm,
           convexity,
           PLOTSVM = FALSE,
           step.plot.LSVM = 1,
           hyperplanes = FALSE,
           limit.state.estimate = TRUE)
```

Arguments

X.new	a matrix containing a new data sets
Y.new	a vector containing -1 or +1 that represents the class of each elements of X.new.
X	a matrix containing the data sets
Y	a vector containing -1 or +1 that represents the class of each elements of X.
A.model.lsvm	a matrix containing the parameters of all hyperplanes.
convexity	Either -1 if the set of data associated to the label "-1" is convex or +1 otherwise.
PLOTSVM	A boolean. If TRUE, plot the data.
step.plot.LSVM	A plot is made each step.plot.LSVM steps.
hyperplanes	A boolean. If TRUE, plot the hyperplanes obtained.
limit.state.estimate	A boolean. If TRUE, plot the estimate of the limit state.

Details

updateLSVM allows to make an update of the classifier LSVM.

Value

An object of class `matrix` containing the parameters of a set of hyperplanes

Note

The argument `PLOTSVM` is useful only in dimension 2.

 updateSd

UpdateSd

Description

Update kriging variance when adding new points to the DoE

Usage

```
updateSd(
  X.new,
  integration.points.oldsd,
  model,
  precalc.data,
  integration.points
)
```

Arguments

<code>X.new</code>	the $d \times N$ matrix containing the points added to the model for the update of the kriging variance.
<code>integration.points.oldsd</code>	a vector containing the standard deviation of the points to be added to the meta-model learning database.
<code>model</code>	the current kriging model (a <code>km</code> object).
<code>precalc.data</code>	precomputed data from <code>KrigInv::precomputeUpdateData</code> .
<code>integration.points</code>	points where the updated sd is to be calculated.

Value

a vector containing the kriging sd at points `integration.points`

updateSd.old

UpdateSd.old

Description

UpdateSd.old

Usage

```
updateSd.old(X.new, newdata.oldsd, model, precalc.data, integration.points)
```

Arguments

<code>X.new</code>	the $d \times N$ matrix containing the points added to the model for the update of the kriging variance.
<code>newdata.oldsd</code>	a vector containing the standard deviation of the points to be added to the meta-model learning database.
<code>model</code>	the current kriging model (a <code>km</code> object).
<code>precalc.data</code>	precomputed data from <code>KrigInv::precomputeUpdateData</code> .
<code>integration.points</code>	points where the updated sd is to be calculated.

 UtoX

Iso-probabilistic transformation from U space to X space

Description

UtoX performs an iso-probabilistic transformation from standardized space (U) to physical space (X) according to the NATAF transformation, which requires only to know the means, the standard deviations, the correlation matrix $\rho(X_i, X_j) = \rho_{ij}$ and the marginal distributions of X_i . In standard space, all random variables are uncorrelated standard normal distributed variables whereas they are correlated and defined using the following distribution functions: Normal (or Gaussian), Lognormal, Uniform, Gumbel, Weibull and Gamma.

Usage

```
UtoX(U, input.margin, L0)
```

Arguments

<code>U</code>	a matrix containing the realisation of all random variables in U-space
<code>input.margin</code>	A list containing one or more list defining the marginal distribution functions of all random variables to be used
<code>L0</code>	the lower matrix of the Cholesky decomposition of correlation matrix <code>R0</code> (result of <code>ModifCorrMatrix</code>)

Details

Supported distributions are :

- **NORMAL**: distribution, defined by its mean and standard deviation

$$distX <- list(type = "Norm", MEAN = 0.0, STD = 1.0, NAME = "X1")$$

- **LOGNORMAL**: distribution, defined by its internal parameters `P1=meanlog` and `P2=sdlog` (`plnorm`)

$$distX <- list(type = "Lnorm", P1 = 10.0, P2 = 2.0, NAME = "X2")$$

- UNIFORM: distribution, defined by its internal parameters P1=min and P2=max ([punif](#))

```
distX <- list(type = "Unif", P1 = 2.0, P2 = 6.0, NAME = "X3")
```

- GUMBEL: distribution, defined by its internal parameters P1 and P2

```
distX <- list(type = 'Gumbel', P1 = 6.0, P2 = 2.0, NAME = 'X4')
```

- WEIBULL: distribution, defined by its internal parameters P1=shape and P2=scale ([pweibull](#))

```
distX <- list(type = 'Weibull', P1 = NULL, P2 = NULL, NAME = 'X5')
```

- GAMMA: distribution, defined by its internal parameters P1=shape and P2=scale ([pgamma](#))

```
distX <- list(type = 'Gamma', P1 = 6.0, P2 = 6.0, NAME = 'X6')
```

- BETA: distribution, defined by its internal parameters P1=shape1 and P2=shapze2 ([pbeta](#))

```
distX <- list(type = 'Beta', P1 = 6.0, P2 = 6.0, NAME = 'X7')
```

Value

X a matrix containing the realisation of all random variables in X-space

  return(G)
}

u0 <- as.matrix(c(1.0,-0.5))
lsf(u0)

```

waarts

A limit-state-function defined by Waarts

Description

The limit-state function is defined by:

$$b1 = 3 + (u_1 - u_2)^2/10 - \text{sign}(u_1 + u_2) * (u_1 + u_2)/\text{sqrt}(2)$$

$$b2 = \text{sign}(u_2 - u_1) * (u_1 - u_2) + 7/\text{sqrt}(2)$$

$$f(u) = \min(b1, b2)$$

Usage

waarts

Format

The function can handle a vector or matrix with column vectors.

WilksFormula	<i>Sample size by Wilks formula</i>
--------------	-------------------------------------

Description

Compute Wilks formula for setting size of a i.i.d. sample for quantile estimation with confidence level or for tolerance intervals

Usage

```
WilksFormula(alpha=0.95,beta=0.95,bilateral=FALSE,order=1)
```

Arguments

alpha	order of the quantile (default = 0.95)
beta	level of the confidence interval (default = 0.95)
bilateral	TRUE for bilateral quantile (default = unilateral = FALSE)
order	order of the Wilks formula (default = 1)

Value

N	The minimal sample size to apply Wilks formula

`XtoU`*From X to standard space*

Description

XtoU lets transform datapoint in the original space X to the standard Gaussian space U with isoprobabilistic transformation.

Usage

```
XtoU(X, input.margin, L0)
```

Arguments

<code>X</code>	the matrix $d \times n$ of the input points
<code>input.margin</code>	A list containing one or more list defining the marginal distribution functions of all random variables to be used
<code>L0</code>	the lower matrix of the Cholesky decomposition of correlation matrix $R0$ (result of ModifCorrMatrix)
