

Package ‘nscancor’

October 13, 2022

Version 0.6.1-25

Title Non-Negative and Sparse CCA

Description Two implementations of canonical correlation analysis (CCA) that are based on iterated regression. By choosing the appropriate regression algorithm for each data domain, it is possible to enforce sparsity, non-negativity or other kinds of constraints on the projection vectors. Multiple canonical variables are computed sequentially using a generalized deflation scheme, where the additional correlation not explained by previous variables is maximized. 'nscancor' is used to analyze paired data from two domains, and has the same interface as the 'cancor' function from the 'stats' package (plus some extra parameters). 'mcancor' is appropriate for analyzing data from three or more domains. See <http://sigg-iten.ch/learningbits/2014/01/20/canonical-correlation-analysis-under-constraints/> and Sigg et al. (2007) [doi:10.1109/MLSP.2007.4414315](https://doi.org/10.1109/MLSP.2007.4414315) for more details.

--------------	-----------

acor	<i>Additional Explained Correlation</i>
------	---

Description

acor computes the additional standard correlation explained by each canonical variable, taking into account the possible non-conjugacy of the canonical vectors. The result of the analysis is returned as a list of class nscancor.

Usage

```
acor(x, xcoef, y, ycoef, xcenter = TRUE, ycenter = TRUE, xscale = FALSE,
     yscale = FALSE)
```

Arguments

x	a numeric matrix which provides the data from the first domain
xcoef	a numeric data matrix with the canonical vectors related to x as its columns.
y	a numeric matrix which provides the data from the second domain
ycoef	a numeric data matrix with the canonical vectors related to y as its columns.
xcenter	a logical value indicating whether the empirical mean of (each column of) x should be subtracted. Alternatively, a vector of length equal to the number of columns of x can be supplied. The value is passed to scale .
ycenter	analogous to xcenter
xscale	a logical value indicating whether the columns of x should be scaled to have unit variance before the analysis takes place. The default is FALSE for consistency with cancor. Alternatively, a vector of length equal to the number of columns of x can be supplied. The value is passed to scale .
yscale	analogous to xscale

Details

The additional correlation is measured after projecting the corresponding canonical vectors to the ortho-complement space spanned by the previous canonical variables. This procedure ensures that the correlation explained by non-conjugate canonical vectors is not counted multiple times. See Mackey (2009) for a presentation of generalized deflation in the context of principal component analysis (PCA), which was adapted here to CCA.

acor is also useful to build a partial CCA model, to be completed with additional canonical variables computed using [nscancor](#).

Value

acor returns a list of class nscancor containing the following elements:

cor	the additional correlation explained by each pair of canonical variables
xcoef	copied from the input arguments
ycoef, ycenter, yscale	copied from the input arguments
xp	the deflated data matrix corresponding to x
yp	analogous to xp

cardinality	<i>Cardinality of Column Vectors</i>
-------------	--------------------------------------

Description

Computes the cardinality (the sum of non-zero elements) of each column of the matrix w.

Usage

```
cardinality(w)
```

Arguments

w a numeric matrix, e.g. xcoef as returned by [nscancor](#)

 macor

Multi-Domain Additional Explained Correlation

Description

macor generalizes [acor](#) to the case of more than two data domains.

Usage

```
macor(x, coef, center = TRUE, scale_ = FALSE)
```

Arguments

x	a list of numeric matrices which contain the data from the different domains
coef	a list of matrices containing the canonical vectors related to each data domain. Each matrix contains the respective canonical vectors as its columns.
center	a list of logical values indicating whether the empirical mean of (each column of) the corresponding data matrix should be subtracted. Alternatively, a list of vectors can be supplied, where each vector specifies the mean to be subtracted from the corresponding data matrix. Each list element is passed to scale .
scale_	a list of logical values indicating whether the columns of the corresponding data matrix should be scaled to have unit variance before the analysis takes place. The default is FALSE for consistency with acor . Alternatively, a list of vectors can be supplied, where each vector specifies the standard deviations used to rescale the columns of the corresponding data matrix. Each list element is passed to scale .

Value

macor returns a list of class `mcancor` with the following elements:

cor	a multi-dimensional array containing the additional correlations explained by each pair of canonical variables. The first two dimensions correspond to the domains, and the third dimension corresponds to the different canonical variables per domain.
coef	copied from the input arguments
center	the list of empirical means used to center the data matrices
scale	the list of empirical standard deviations used to scale the data matrices
xp	the list of deflated data matrices corresponding to x

 mcancor

Non-Negative and Sparse Multi-Domain CCA

Description

Performs a canonical correlation analysis (CCA) on multiple data domains, where constraints such as non-negativity or sparsity are enforced on the canonical vectors. The result of the analysis is returned as a list of class `mcancor`.

Usage

```
mcancor(x, center = TRUE, scale_ = FALSE, nvar = min(sapply(x, dim)),
        predict, cor_tol = NULL, nrestart = 10, iter_tol = 0, iter_max = 50,
        partial_model = NULL, verbosity = 0)
```

Arguments

<code>x</code>	a list of numeric matrices which contain the data from the different domains
<code>center</code>	a list of logical values indicating whether the empirical mean of (each column of) the corresponding data matrix should be subtracted. Alternatively, a list of vectors can be supplied, where each vector specifies the mean to be subtracted from the corresponding data matrix. Each list element is passed to <code>scale</code> .
<code>scale_</code>	a list of logical values indicating whether the columns of the corresponding data matrix should be scaled to have unit variance before the analysis takes place. The default is <code>FALSE</code> for consistency with <code>nscancor</code> . Alternatively, a list of vectors can be supplied, where each vector specifies the standard deviations used to rescale the columns of the corresponding data matrix. Each list element is passed to <code>scale</code> .
<code>nvar</code>	the number of canonical variables to be computed for each domain. With the default setting, canonical variables are computed until at least one data matrix is fully deflated.
<code>predict</code>	a list of regression functions to predict the sum of the canonical variables of all other domains. The formal arguments for each regression function are the design matrix <code>x</code> corresponding to the data from the current domain, the regression target <code>sc</code> as the sum of the canonical variables for all other domains, and <code>cc</code> as a counter of which canonical variable is currently computed (e.g. for enforcing different constraints for subsequent canonical vectors of a given domain). See the examples for an illustration.
<code>cor_tol</code>	a threshold indicating the magnitude below which canonical variables should be omitted. Variables are omitted if the sum of all their correlations are less than or equal to <code>cor_tol</code> times the sum of all correlations of the first canonical variables of all domains. With the default <code>NULL</code> setting, no variables are omitted.
<code>nrestart</code>	the number of random restarts for computing the canonical variables via iterated regression steps. The solution achieving maximum explained correlation over all random restarts is kept. A value greater than one can help to avoid poor local maxima.

<code>iter_tol</code>	If the relative change of the objective is less than <code>iter_tol</code> between iterations, the procedure is assumed to have converged to a local optimum.
<code>iter_max</code>	the maximum number of iterations to be performed. The procedure is terminated if either the <code>iter_tol</code> or the <code>iter_max</code> criterion is satisfied.
<code>partial_model</code>	NULL or an object of class <code>mcancor</code> . The computation can be continued from a partial model by providing an <code>mcancor</code> object (either from a previous run of this function or from <code>macor</code>) and setting <code>nvar</code> to a value greater than the number of canonical variables contained in the partial model. See the examples for an illustration.
<code>verbosity</code>	an integer specifying the verbosity level. Greater values result in more output, the default is to be quiet.

Details

`mcancor` generalizes `nscancor` to the case where more than two data domains are available for an analysis. Its objective is to maximize the sum of all pairwise correlations of the canonical variables.

Value

`mcancor` returns a list of class `mcancor` with the following elements:

<code>cor</code>	a multi-dimensional array containing the additional correlations explained by each pair of canonical variables. The first two dimensions correspond to the domains, and the third dimension corresponds to the different canonical variables per domain (see also <code>macor</code>).
<code>coef</code>	a list of matrices containing the canonical vectors related to each data domain. The canonical vectors are stored as the columns of each matrix.
<code>center</code>	the list of empirical means used to center the data matrices
<code>scale</code>	the list of empirical standard deviations used to scale the data matrices
<code>xp</code>	the list of deflated data matrices corresponding to <code>x</code>

    requireNamespace("PMA", quietly = TRUE)) {

  data(breastdata, package="PMA")

  set.seed(1)

  # Three data domains: a subset of genes, and CGH spots for the first and
  # second chromosome
  x <- with(breastdata,
            list(t(rna)[ , 1:100], t(dna)[ , chrom == 1], t(dna)[ , chrom == 2])
```

```

)

# Sparse regression functions with different cardinalities for different domains
generate_predict <- function(dfmax) {
  force(dfmax)
  return(
    function(x, sc, cc) {
      en <- glmnet::glmnet(x, sc, alpha = 0.05, intercept = FALSE, dfmax = dfmax)
      W <- coef(en)
      return(W[2:nrow(W), ncol(W)])
    }
  )
}
predict <- lapply(c(20, 10, 10), generate_predict)

# Compute two canonical variables per domain
mcc <- mcancor(x, predict = predict, nvar = 2)

# Compute another canonical variable for each domain
mcc <- mcancor(x, predict = predict, nvar = 3, partial_model = mcc)
}

```

nscancor

Non-Negative and Sparse CCA

Description

Performs a canonical correlation analysis (CCA) where constraints such as non-negativity or sparsity are enforced on the canonical vectors. The result of the analysis is returned as a list of class `nscancor`, which contains a superset of the elements returned by `cancor`.

Usage

```

nscancor(x, y, xcenter = TRUE, ycenter = TRUE, xscale = FALSE,
         yscale = FALSE, nvar = min(dim(x), dim(y)), xpredict, ypredict,
         cor_tol = NULL, nrestart = 10, iter_tol = 0, iter_max = 50,
         partial_model = NULL, verbosity = 0)

```

Arguments

<code>x</code>	a numeric matrix which provides the data from the first domain
<code>y</code>	a numeric matrix which provides the data from the second domain
<code>xcenter</code>	a logical value indicating whether the empirical mean of (each column of) <code>x</code> should be subtracted. Alternatively, a vector of length equal to the number of columns of <code>x</code> can be supplied. The value is passed to <code>scale</code> .
<code>ycenter</code>	analogous to <code>xcenter</code>

<code>xscale</code>	a logical value indicating whether the columns of <code>x</code> should be scaled to have unit variance before the analysis takes place. The default is <code>FALSE</code> for consistency with <code>cancor</code> . Alternatively, a vector of length equal to the number of columns of <code>x</code> can be supplied. The value is passed to <code>scale</code> .
<code>yscale</code>	analogous to <code>xscale</code>
<code>nvar</code>	the number of canonical variables to be computed for each domain. With the default setting, canonical variables are computed until either <code>x</code> or <code>y</code> is fully deflated.
<code>xpredict</code>	the regression function to predict the canonical variable for <code>x</code> , given <code>y</code> . The formal arguments are the design matrix <code>y</code> , the regression target <code>xc</code> as the current canonical variable for <code>x</code> , and <code>cc</code> as a counter of the current pair of canonical variables (e.g. for enforcing different constraints for different canonical vectors). See the examples for an illustration.
<code>ypredict</code>	analogous to <code>xpredict</code>
<code>cor_tol</code>	a threshold indicating the magnitude below which canonical variables should be omitted. Variables are omitted if their explained correlations are less than or equal to <code>cor_tol</code> times the correlation of the first pair of canonical variables. With the default <code>NULL</code> setting, no variables are omitted.
<code>nrestart</code>	the number of random restarts for computing the canonical variables via iterated regression steps. The solution achieving maximum explained correlation over all random restarts is kept. A value greater than one can help to avoid poor local maxima.
<code>iter_tol</code>	If the relative change of the objective is less than <code>iter_tol</code> between iterations, the procedure is assumed to have converged to a local optimum.
<code>iter_max</code>	the maximum number of iterations to be performed. The procedure is terminated if either the <code>iter_tol</code> or the <code>iter_max</code> criterion is satisfied.
<code>partial_model</code>	<code>NULL</code> or an object of class <code>nscancor</code> . The computation can be continued from a partial model by providing an <code>nscancor</code> object (either from a previous run of this function or from <code>acor</code>) and setting <code>nvar</code> to a value greater than the number of canonical variables contained in the partial model. See the examples for an illustration.
<code>verbosity</code>	an integer specifying the verbosity level. Greater values result in more output, the default is to be quiet.

Details

`nscancor` computes the canonical vectors (called `xcoef` and `ycoef`) using iterated regression steps, where the constraints suitable for each domain are enforced by choosing the appropriate regression method. See Sigg et al. (2007) for an early application of the principle (not yet including generalized deflation).

Because constrained canonical vectors no longer correspond to true eigenvectors of the cross-covariance matrix and are usually not pairwise conjugate (i.e. the canonical variables are not uncorrelated), special attention needs to be paid when computing more than a single pair of canonical vectors. `nscancor` implements a generalized deflation (GD) scheme which builds on GD for PCA as proposed by Mackey (2009). For each domain, a basis of the space spanned by the previous

canonical variables is computed. Then, the correlation of the current pair of canonical variables is maximized after projecting each current canonical vector to the ortho-complement space of its respective basis. This procedure maximizes the additional correlation not explained by previous canonical variables, and is identical to standard CCA if the canonical vectors are the eigenvectors of the cross-covariance matrix.

See the references for further details.

Value

nscancor returns a list of class nscancor containing the following elements:

cor	the additional correlation explained by each pair of canonical variables, see acor .
xcoef	the matrix containing the canonical vectors related to x as its columns
ycoef	analogous to xcoef
xcenter	if xcenter is TRUE the centering vector, else the zero vector (in accordance with cancor)
ycenter	analogous to xcenter
xscale	if xscale is TRUE the scaling vector, else FALSE
yscale	analogous to xscale
xp	the deflated data matrix corresponding to x
yp	analogous to xp
