Cars

Consumer reports car data: dimensions

Description

A data frame containing 11 variables with different dimensions of 111 cars

Usage

data(Cars)

Format

A data frame with 111 observations on the following 11 variables.

length a numeric vector wheelbase a numeric vector width a numeric vector height a numeric vector Cars 3

```
front.hd a numeric vector
rear.hd a numeric vector
front.leg a numeric vector
rear.seating a numeric vector
front.shoulder a numeric vector
rear.shoulder a numeric vector
luggage a numeric vector
```

Source

Consumer reports. (April 1990). http://backissues.com/issue/Consumer-Reports-April-1990, pp. 235–288.

References

Chambers, J. M. and Hastie, T. J. (1992). Statistical models in S. Cole, Pacific Grove, CA: Wadsworth and Brooks, pp. 46–47.

M. Hubert, P. J. Rousseeuw, K. Vanden Branden (2005), ROBPCA: A new approach to robust principal components analysis, *Technometrics*, **47**, 64–79.

Examples

```
data(Cars)
## Plot a pairwise scaterplot matrix
   pairs(Cars[,1:6])
   mcd <- CovMcd(Cars[,1:6])</pre>
   plot(mcd, which="pairs")
## Start with robust PCA
    pca <- PcaHubert(Cars, k=ncol(Cars), kmax=ncol(Cars))</pre>
   pca
## Compare with the classical PCA
    prcomp(Cars)
   PcaClassic(Cars, k=ncol(Cars), kmax=ncol(Cars))
## If you want to print the scores too, use
    print(pca, print.x=TRUE)
## Using the formula interface
   PcaHubert(~., data=Cars, k=ncol(Cars), kmax=ncol(Cars))
## To plot the results:
                                  # distance plot
   plot(pca)
```

4 CSimca

```
pca2 <- PcaHubert(Cars, k=4)
plot(pca2)  # PCA diagnostic plot (or outlier map)

## Use the standard plots available for prcomp and princomp
screeplot(pca)  # it is interesting with all variables
biplot(pca)  # for biplot we need more than one PCs

## Restore the covraiance matrix
py <- PcaHubert(Cars, k=ncol(Cars), kmax=ncol(Cars))
cov.1 <- py@loadings %*% diag(py@eigenvalues) %*% t(py@loadings)
cov.1</pre>
```

CSimca

Classification in high dimensions based on the (classical) SIMCA method

Description

CSimca performs the (classical) SIMCA method. This method classifies a data matrix x with a known group structure. To reduce the dimension on each group a PCA analysis is performed. Afterwards a classification rule is developed to determine the assignment of new observations.

Usage

```
CSimca(x, ...)
## Default S3 method:
CSimca(x, grouping, prior=proportions, k, kmax = ncol(x),
    tol = 1.0e-4, trace=FALSE, ...)
## S3 method for class 'formula'
CSimca(formula, data = NULL, ..., subset, na.action)
```

Arguments

formula	a formula of the form y^x , it describes the response and the predictors. The formula can be more complicated, such as $y^2\log(x)+z$ etc (see formula for more details). The response should be a factor representing the response variable, or any vector that can be coerced to such (such as a logical variable).
data	an optional data frame (or similar: see model.frame) containing the variables in the formula formula.
subset	an optional vector used to select rows (observations) of the data matrix x.
na.action	a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The default is na.omit.
х	a matrix or data frame containing the explanatory variables (training set).
grouping	grouping variable: a factor specifying the class for each observation.

CSimca 5

prior prior probabilities, default to the class proportions for the training set.
tol tolerance
k number of principal components to compute. If k is missing, or k = 0, the algorithm itself will determine the number of components by finding such k that $l_k/l_1 >= 10.E - 3$ and $\sum_{j=1}^k l_j/\sum_{j=1}^r l_j >= 0.8$. It is preferable to investigate the scree plot in order to choose the number of components and then run again. Default is k=0.
kmax maximal number of principal components to compute. Default is kmax=10. If k is provided, kmax does not need to be specified, unless k is larger than 10.
trace whether to print intermediate results. Default is trace = FALSE

... arguments passed to or from other methods.

Details

CSimca, serving as a constructor for objects of class CSimca-class is a generic function with "formula" and "default" methods.

SIMCA is a two phase procedure consisting of PCA performed on each group separately for dimension reduction followed by classification rules built in the lower dimensional space (note that the dimension in each group can be different). In original SIMCA new observations are classified by means of their deviations from the different PCA models. Here (and also in the robust versions implemented in this package) the classification rules will be obtained using two popular distances arising from PCA - orthogonal distances (OD) and score distances (SD). For the definition of these distances, the definition of the cutoff values and the standartization of the distances see Vanden Branden K, Hubert M (2005) and Todorov and Filzmoser (2009).

Value

An S4 object of class CSimca-class which is a subclass of of the virtual class Simca-class.

Examples

```
data(pottery)
dim(pottery)  # 27 observations in 2 classes, 6 variables
head(pottery)
```

6 CSimca-class

```
## Build the SIMCA model. Use RSimca for a robust version
cs <- CSimca(origin~., data=pottery)
cs
summary(cs)

## generate a sample from the pottery data set -
## this will be the "new" data to be predicted
smpl <- sample(1:nrow(pottery), 5)
test <- pottery[smpl, -7]  # extract the test sample. Remove the last (grouping) variable
print(test)

## predict new data
pr <- predict(cs, newdata=test)
pr@classification</pre>
```

CSimca-class

Class "CSimca" - classification in high dimensions based on the (classical) SIMCA method

Description

The class CSimca represents the SIMCA algorithm for classification in high dimensions. The objects of class CSImca contain the results of the SIMCA method.

Objects from the Class

Objects can be created by calls of the form new("CSImca", ...) but the usual way of creating CSimca objects is a call to the function CSimca() which serves as a constructor.

Slots

```
call: the (matched) function call.

prior: prior probabilities used, default to group proportions

counts: number of observations in each class

pcaobj: A list of Pca objects - one for each group

k: Object of class "numeric" number of (choosen) principal components
```

flag: Object of class "Uvector" The observations whose score distance is larger than cutoff.sd or whose orthogonal distance is larger than cutoff.od can be considered as outliers and receive a flag equal to zero. The regular observations receive a flag 1

X: the training data set (same as the input parameter x of the constructor function)

grp: grouping variable: a factor specifying the class for each observation.

getWeight-methods 7

Extends

```
Class "Simca", directly.
```

Methods

No methods defined with class "CSimca" in the signature.

getWeight-methods

Accessor methods to the essential slots of Outlier and its subclasses

Description

Accessor methods to the essential slots of Outlier and its subclasses

Methods

obj = "Outlier" generic functions - see getWeight, getOutliers, getClassLabels, getCutoff

8 kibler

kibler

1985 Auto Imports Database

Description

The original data set kibler.orig consists of three types of entities: (a) the specification of an auto in terms of various characteristics, (b) its assigned insurance risk rating and (c) its normalized losses in use as compared to other cars.

The second rating corresponds to the degree to which the auto is more risky than its price indicates. Cars are initially assigned a risk factor symbol associated with its price. Then, if it is more risky (or less), this symbol is adjusted by moving it up (or down) the scale. Actuarians call this process "symboling". A value of +3 indicates that the auto is risky, -3 that it is probably pretty safe.

The third factor is the relative average loss payment per insured vehicle year. This value is normalized for all autos within a particular size classification (two-door small, station wagons, sports/speciality, etc...), and represents the average loss per car per year.

Usage

data(kibler)

Format

A data frame with 195 observations on the following 14 variables. The original data set (also available as kibler.orig) contains 205 cases and 26 variables of which 15 continuous, 1 integer and 10 nominal. The non-numeric variables and variables with many missing values were removed. Cases with missing values were removed too.

symboling a numeric vector
wheel-base a numeric vector
length a numeric vector
width a numeric vector
height a numeric vector
curb-weight a numeric vector
bore a numeric vector
stroke a numeric vector
compression-ratio a numeric vector
horsepower a numeric vector
peak-rpm a numeric vector
city-mpg a numeric vector
highway-mpg a numeric vector

kibler 9

Details

The original data set contains 205 cases and 26 variables of which 15 continuous, 1 integer and 10 nominal. The non-numeric variables and variables with many missing values were removed. Cases with missing values were removed too. Thus the data set remains with 195 cases and 14 variables.

## End(Not run)</pre>
```

Outlier-class

Class "Outlier" – a base class for outlier identification

Description

The class Outlier represents the results of outlier identification.

Objects from the Class

A virtual Class: No objects may be created from it.

Slots

```
call: Object of class "language"
counts: Number of observations in each class
grp: Grouping variable
wt: Vector of weights
flag: 0/1 flags identifying the outliers
method: A character string specifying the method used to identify the outliers. In case of OutlierMahdist
class this is the name of the robust estimator of multivariate location and covariance matrix
used
singularity: a list with singularity information for the covariance matrix (or NULL if not singular)
```

Methods

```
getClassLabels Returns a vector with indices for a given class
getDistance Returns a vector containing the computed distances
getFlag Returns the flags identifying the outliers
getOutliers Returns a vector with the indices of the identified outliers
getWeight Returns a vector of weights
plot
show
```

OutlierMahdist 11

Author(s)

Valentin Todorov <valentin.todorov@chello.at>

References

Todorov V & Filzmoser P (2009). An Object Oriented Framework for Robust Multivariate Analysis. *Journal of Statistical Software*, **32**(3), 1–47. doi: 10.18637/jss.v032.i03.

Filzmoser P & Todorov V (2013). Robust tools for the imperfect world, *Information Sciences* **245**, 4–20. doi: 10.1016/j.ins.2012.10.017.

Examples

```
OutlierMahdist

Outlier identification using robust (mahalanobis) distances based on robust multivariate location and covariance matrix
```

Description

This function uses the Mahalanobis distance as a basis for multivariate outlier detection. The standard method for multivariate outlier detection is robust estimation of the parameters in the Mahalanobis distance and the comparison with a critical value of the Chi2 distribution (Rousseeuw and Van Zomeren, 1990).

Usage

```
OutlierMahdist(x, ...)

## Default S3 method:
OutlierMahdist(x, grouping, control, trace=FALSE, ...)

## S3 method for class 'formula'
OutlierMahdist(formula, data, ..., subset, na.action)
```

Arguments

formula	a formula with no response variable, referring only to numeric variables.
data	an optional data frame (or similar: see model.frame) containing the variables in the formula formula.
subset	an optional vector used to select rows (observations) of the data matrix x.
na.action	a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The default is na.omit.
• • •	arguments passed to or from other methods.
X	a matrix or data frame.
grouping	grouping variable: a factor specifying the class for each observation.

12 OutlierMahdist

control a control object (S4) for one of the available control classes, e.g. CovControlMcd-class,

CovControlOgk-class, CovControlSest-class, etc., containing estimation options. The class of this object defines which estimator will be used. Alternatively a character string can be specified which names the estimator - one of auto, sde, mcd, ogk, m, mve, sfast, surreal, bisquare, rocke. If 'auto' is specified or the argument is missing, the function will select the estimator (see below for

details)

trace whether to print intermediate results. Default is trace = FALSE

Details

If the data set consists of two or more classes (specified by the grouping variable grouping) the proposed method iterates through the classes present in the data, separates each class from the rest and identifies the outliers relative to this class, thus treating both types of outliers, the mislabeled and the abnormal samples in a homogenous way.

The estimation method is selected by the control object control. If a character string naming an estimator is specified, a new control object will be created and used (with default estimation options). If this argument is missing or a character string 'auto' is specified, the function will select the robust estimator according to the size of the dataset - for details see CovRobust.

Value

An S4 object of class OutlierMahdist which is a subclass of the virtual class Outlier.

showClass("OutlierMahdist")
```

OutlierPCDist

Outlier identification in high dimensions using the PCDIST algorithm

Description

The function implements a simple, automatic outlier detection method suitable for high dimensional data that treats each class independently and uses a statistically principled threshold for outliers. The algorithm can detect both mislabeled and abnormal samples without reference to other classes.

Usage

```
OutlierPCDist(x, ...)
  ## Default S3 method:
OutlierPCDist(x, grouping, control, k, explvar, trace=FALSE, ...)
  ## S3 method for class 'formula'
OutlierPCDist(formula, data, ..., subset, na.action)
```

Arguments

formula	a formula with no response variable, referring only to numeric variables.
data	an optional data frame (or similar: see $model.frame$) containing the variables in the formula formula.
subset	an optional vector used to select rows (observations) of the data matrix x.
na.action	a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The default is na.omit.
	arguments passed to or from other methods.
x	a matrix or data frame.
grouping	grouping variable: a factor specifying the class for each observation.

OutlierPCDist 15

a control object (S4) for one of the available control classes, e.g. CovControlMcd-class, CovControlOgk-class, CovControlSest-class, etc., containing estimation options. The class of this object defines which estimator will be used. Alternatively a character string can be specified which names the estimator - one of auto, sde, mcd, ogk, m, mve, sfast, surreal, bisquare, rocke. If 'auto' is specified or the argument is missing, the function will select the estimator (see below for details)

k

Number of components to select for PCA. If missing, the number of components will be calculated automatically

explvar

Minimal explained variance to be used for calculation of the number of components in PCA. If explvar is not provided, automatic dimensionality selection using profile likelihood, as proposed by Zhu and Ghodsi will be used.

trace whether to print intermediate results. Default is trace = FALSE

Details

If the data set consists of two or more classes (specified by the grouping variable grouping) the proposed method iterates through the classes present in the data, separates each class from the rest and identifies the outliers relative to this class, thus treating both types of outliers, the mislabeled and the abnormal samples in a homogenous way.

The first step of the algorithm is dimensionality reduction using (classical) PCA. The number of components to select can be provided by the user but if missing, the number of components will be calculated either using the provided minimal explained variance or by the automatic dimensionality selection using profile likelihood, as proposed by Zhu and Ghodsi.

Value

An S4 object of class OutlierPCDist which is a subclass of the virtual class Outlier.

OutlierPCOut

Outlier identification in high dimensions using the PCOUT algorithm

Description

The function implements a computationally fast procedure for identifying outliers that is particularly effective in high dimensions. This algorithm utilizes simple properties of principal components to identify outliers in the transformed space, leading to significant computational advantages for high-dimensional data. This approach requires considerably less computational time than existing methods for outlier detection, and is suitable for use on very large data sets. It is also capable of analyzing the data situation commonly found in certain biological applications in which the number of dimensions is several orders of magnitude larger than the number of observations.

Usage

```
OutlierPCOut(x, ...)
## Default S3 method:
OutlierPCOut(x, grouping, explvar=0.99, trace=FALSE, ...)
## S3 method for class 'formula'
OutlierPCOut(formula, data, ..., subset, na.action)
```

Arguments

formula	a formula with no response variable, referring only to numeric variables.
data	an optional data frame (or similar: see model.frame) containing the variables in the formula formula.
subset	an optional vector used to select rows (observations) of the data matrix x.
na.action	a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The default is na.omit.
	arguments passed to or from other methods.

18 OutlierPCOut

x a matrix or data frame.

grouping grouping variable: a factor specifying the class for each observation.

explvar a numeric value between 0 and 1 indicating how much variance should be cov-

ered by the robust PCs (default to 0.99)

trace whether to print intermediate results. Default is trace = FALSE

Details

If the data set consists of two or more classes (specified by the grouping variable grouping) the proposed method iterates through the classes present in the data, separates each class from the rest and identifies the outliers relative to this class, thus treating both types of outliers, the mislabeled and the abnormal samples in a homogenous way.

Value

An S4 object of class OutlierPCOut which is a subclass of the virtual class Outlier.

OutlierSign1

OutlierSign1	Outlier identification in high dimensions using the SIGN1 algorithm
	· · · · · · · · · · · · · · · · · · ·

Description

Fast algorithm for identifying multivariate outliers in high-dimensional and/or large datasets, using spatial signs, see Filzmoser, Maronna, and Werner (CSDA, 2007). The computation of the distances is based on Mahalanobis distances.

Usage

```
OutlierSign1(x, ...)
  ## Default S3 method:
OutlierSign1(x, grouping, qcrit = 0.975, trace=FALSE, ...)
  ## S3 method for class 'formula'
OutlierSign1(formula, data, ..., subset, na.action)
```

Arguments

formula	a formula with no response variable, referring only to numeric variables.
data	an optional data frame (or similar: see model.frame) containing the variables in the formula formula.
subset	an optional vector used to select rows (observations) of the data matrix x.
na.action	a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The default is na.omit.
	arguments passed to or from other methods.
x	a matrix or data frame.
grouping	grouping variable: a factor specifying the class for each observation.
qcrit	a numeric value between 0 and 1 indicating the quantile to be used as critical value for outlier detection (default to 0.975).
trace	whether to print intermediate results. Default is trace = FALSE

Details

Based on the robustly sphered and normed data, robust principal components are computed. These are used for computing the covariance matrix which is the basis for Mahalanobis distances. A critical value from the chi-square distribution is then used as outlier cutoff.

Value

An S4 object of class OutlierSign1 which is a subclass of the virtual class Outlier.

OutlierSign2

Outlier identification in high dimensions using the SIGN2 algorithm

Description

Fast algorithm for identifying multivariate outliers in high-dimensional and/or large datasets, using spatial signs, see Filzmoser, Maronna, and Werner (CSDA, 2007). The computation of the distances is based on principal components.

Usage

```
OutlierSign2(x, ...)
  ## Default S3 method:
OutlierSign2(x, grouping, qcrit = 0.975, explvar=0.99, trace=FALSE, ...)
  ## S3 method for class 'formula'
OutlierSign2(formula, data, ..., subset, na.action)
```

OutlierSign2 23

Arguments

formula	a formula with no response variable, referring only to numeric variables.
data	an optional data frame (or similar: see $model.frame$) containing the variables in the formula formula.
subset	an optional vector used to select rows (observations) of the data matrix \boldsymbol{x} .
na.action	a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The default is na.omit.
	arguments passed to or from other methods.
x	a matrix or data frame.
grouping	grouping variable: a factor specifying the class for each observation.
explvar	a numeric value between 0 and 1 indicating how much variance should be covered by the robust PCs. Default is 0.99 .
qcrit	a numeric value between 0 and 1 indicating the quantile to be used as critical value for outlier detection. Default is 0.975 .
trace	whether to print intermediate results. Default is trace = FALSE

Details

Based on the robustly sphered and normed data, robust principal components are computed which are needed for determining distances for each observation. The distances are transformed to approach chi-square distribution, and a critical value is then used as outlier cutoff.

Value

An S4 object of class OutlierSign2 which is a subclass of the virtual class Outlier.

PredictSosDisc-class Class "PredictSosDisc" - prediction of "SosDisc" objects

Description

The prediction of a "SosDisc" object

Objects from the Class

Objects can be created by calls of the form new("PredictSosDisc", ...) but most often by invoking predict() on a "SosDisc" object. They contain values meant for printing by show()

Slots

classification: Object of class "factor" representing the predicted classification

mahadist2: A "matrix" containing the squared robust Mahalanobis distances to each group center in the subspace (see Details).

w: A "vector" containing the weights derived from robust Mahalanobis distances to the closest group center (see Details).

Details

For the prediction of the class membership a two step approach is taken. First, the newdata are scaled and centered (by obj@scale and obj@center) and multiplied by obj@beta for dimension reduction. Then the classification of the transformed data is obtained by prediction with the Linda object obj@fit. The Mahalanobis distances to the closest group center in this subspace is used to derive case weights w. Observations where the squared robust mahalanobis distance is larger than the 0.975 quantile of the chi-square distribution with Q degrees of freedom receive weight zero, all others weight one.

Methods

show signature(object = "PredictSosDisc"): Prints the results.

RSimca

Robust classification in high dimensions based on the SIMCA method

Description

RSimca performs a robust version of the SIMCA method. This method classifies a data matrix x with a known group structure. To reduce the dimension on each group a robust PCA analysis is performed. Afterwards a classification rule is developed to determine the assignment of new observations.

28 RSimca

Usage

Arguments

formula a formula of the form y~x, it describes the response and the predictors. The formula can be more complicated, such as y~log(x)+z etc (see formula for more details). The response should be a factor representing the response variable, or

any vector that can be coerced to such (such as a logical variable).

data an optional data frame (or similar: see model.frame) containing the variables

in the formula formula.

subset an optional vector used to select rows (observations) of the data matrix x.

na.action a function which indicates what should happen when the data contain NAs. The

default is set by the na.action setting of options, and is na.fail if that is

unset. The default is na.omit.

x a matrix or data frame containing the explanatory variables (training set).

grouping grouping variable: a factor specifying the class for each observation.

prior prior probabilities, default to the class proportions for the training set.

tol tolerance

control a control object (S4) for specifying one of the available PCA estimation meth-

ods and containing estimation options. The class of this object defines which estimator will be used. Alternatively a character string can be specified which names the estimator - one of auto, hubert, locantore, grid, proj. If 'auto' is specified or the argument is missing, the function will select the estimator (see below

for details)

alpha this parameter measures the fraction of outliers the algorithm should resist. In

MCD alpha controls the size of the subsets over which the determinant is minimized, i.e. alpha*n observations are used for computing the determinant. Al-

lowed values are between 0.5 and 1 and the default is 0.5.

k number of principal components to compute. If k is missing, or k = 0, the al-

gorithm itself will determine the number of components by finding such k that $l_k/l_1 >= 10.E-3$ and $\sum_{j=1}^k l_j/\sum_{j=1}^r l_j >= 0.8$. It is preferable to investigate the scree plot in order to choose the number of components and then run again.

Default is k=0.

kmax maximal number of principal components to compute. Default is kmax=10. If k

is provided, kmax does not need to be specified, unless k is larger than 10.

trace whether to print intermediate results. Default is trace = FALSE

... arguments passed to or from other methods.

RSimca 29

Details

RSimca, serving as a constructor for objects of class RSimca-class is a generic function with "formula" and "default" methods.

SIMCA is a two phase procedure consisting of PCA performed on each group separately for dimension reduction followed by classification rules built in the lower dimensional space (note that the dimension in each group can be different). Instead of classical PCA robust alternatives will be used. Any of the robust PCA methods available in package Pca-class can be used through the argument control. In original SIMCA new observations are classified by means of their deviations from the different PCA models. Here the classification rules will be obtained using two popular distances arising from PCA - orthogonal distances (OD) and score distances (SD). For the definition of these distances, the definition of the cutoff values and the standartization of the distances see Vanden Branden K, Hubert M (2005) and Todorov and Filzmoser (2009).

Value

An S4 object of class RSimca-class which is a subclass of of the virtual class Simca-class.

30 RSimca-class

pr@classification

RSimca-class	Class "RSimca" – robust classification in high dimensions	 S
	based on the SIMCA method	

Description

The class RSimca represents robust version of the SIMCA algorithm for classification in high dimensions. The objects of class RSImca contain the results of the robust SIMCA method.

Objects from the Class

Objects can be created by calls of the form new("RSImca", ...) but the usual way of creating RSimca objects is a call to the function RSimca() which serves as a constructor.

Slots

```
call: the (matched) function call.
prior: prior probabilities used, default to group proportions
counts: number of observations in each class
pcaobj: A list of Pca objects - one for each group
k: Object of class "numeric" number of (choosen) principal components
```

flag: Object of class "Uvector" The observations whose score distance is larger than cutoff.sd or whose orthogonal distance is larger than cutoff.od can be considered as outliers and receive a flag equal to zero. The regular observations receive a flag 1

X: the training data set (same as the input parameter x of the constructor function)

grp: grouping variable: a factor specifying the class for each observation.

Extends

```
Class "Simca", directly.
```

Methods

Examples

showClass("Simca")

SosDisc-class

Class "SosDisc" - virtual base class for all classic and robust SosDisc classes representing the results of the robust and sparse multigroup classification by the optimal scoring approach

Description

Robust and sparse multigroup classification by the optimal scoring approach. The class SosDisc searves as a base class for deriving all other classes representing the results of the robust and sparse multigroup classification by the optimal scoring approach.

Details

The sparse optimal scoring problem (Clemmensen et al, 2011): for h = 1, ..., Q

$$\min_{\beta_h,\theta_h} \frac{1}{n} \|Y\theta_h - X\beta_h\|_2^2 + \lambda \|\beta_h\|_1$$

subject to

$$\frac{1}{n} \theta_h^T Y^T Y \theta_h = 1, \quad \theta_h^T Y^T Y \theta_l = 0 \quad \forall l < h.$$

SosDisc-class 33

where X deontes the robustly centered and scaled input matrix x (or alternatively the predictors from formular) and Y is an dummy matrix coding die classmemberships from grouping.

For each h this problem can be solved interatively for β_h and θ_h . In order to obtain robust estimates, β_h is estimated with reweighted sparse least trimmed squares regression (Alfons et al, 2013) and θ_h with least absolut deviation regression in the first two iterations. To speed up the following repetitions an iterative down-weighting of observations with large residuals is combined with the iterative estimation of the optimal scoring coefficients with their classical estimates.

The classification model is estimated on the low dimensional sparse subspace $X[\beta_1,...,\beta_Q]$ with robust LDA (Linda).

Objects from the Class

A virtual Class: No objects may be created from it.

Slots

call: The (matched) function call.

prior: Prior probabilities; same as input parameter.

counts: Number of observations in each class.

beta: Object of class "matrix": Q coefficient vectors of the predictor matrix from optimal scoring (see Details); rows corespond to variables listed in varnames.

theta: Object of class "matrix": Q coefficient vectors of the dummy matrix for class coding from optimal scoring (see Details).

lambda: Non-negative tuning paramer from L1 norm penaly; same as input parameter

varnames: Character vector: Names of included predictor variables (variables where at least one beta coefficient is non-zero).

center: Centering vector of the input predictors (coordinate wise median).

scale: Scaling vector of the input predictors (mad).

fit: Object of class "Linda": Linda model (robust LDA model) estimated in the low dimensional subspace $X[\beta_1,...,\beta_Q]$ (see Details)

mahadist2: These will go later to Linda object: squared robust Mahalanobis distance (calculated with estimates from Linda, with common covariance structure of all groups) of each observation to its group center in the low dimensional subspace $X[\beta_1,...,\beta_Q]$ (see Details).

wlinda: These will go later to Linda object: 0-1 weights derived from mahadist2; observations where the squred robust Mahalanobis distance is larger than the 0.975 quantile of the chi-square distribution with Q degrees of freedom resive weight zero.

X: The training data set (same as the input parameter x of the constructor function)

grp: Grouping variable: a factor specifying the class for each observation (same as the input parameter grouping)

Methods

predict signature(object = "SosDisc"): calculates prediction using the results in object. An optional data frame or matrix in which to look for variables with which to predict. If omitted, the training data set is used. If the original fit used a formula or a data frame or a matrix with column names, newdata must contain columns with the same names.

34 SosDiscClassic-class

```
show signature(object = "SosDisc"): prints the results
summary signature(object = "SosDisc"): prints summary information
```

SosDiscClassic-class Class SosDiscClassic - sparse multigroup classification by the optimal scoring approach

Description

Sparse multigroup classification by the optimal scoring approach.

Objects from the Class

Objects can be created by calls of the form new("SosDiscClassic", ...) but the usual way of creating SosDiscClassic objects is a call to the function SosDiscRobust() which serves as a constructor.

Slots

call: The (matched) function call.

prior: Prior probabilities; same as input parameter.

counts: Number of observations in each class.

beta: Object of class "matrix": Q coefficient vectors of the predictor matrix from optimal scoring (see Details); rows corespond to variables listed in varnames.

theta: Object of class "matrix": Q coefficient vectors of the dummy matrix for class coding from optimal scoring (see Details).

lambda: Non-negative tuning paramer from L1 norm penaly; same as input parameter

varnames: Character vector: Names of included predictor variables (variables where at least one beta coefficient is non-zero).

SosDiscClassic-class 35

- center: Centering vector of the input predictors (coordinate wise median).
- scale: Scaling vector of the input predictors (mad).
- fit: Object of class "Linda": Linda model (robust LDA model) estimated in the low dimensional subspace $X[\beta_1,...,\beta_Q]$ (see Details)
- mahadist2: These will go later to Linda object: squared robust Mahalanobis distance (calculated with estimates from Linda, with common covariance structure of all groups) of each observation to its group center in the low dimensional subspace $X[\beta_1,...,\beta_Q]$ (see Details).
- wlinda: These will go later to Linda object: 0-1 weights derived from mahadist2; observations where the squred robust Mahalanobis distance is larger than the 0.975 quantile of the chi-square distribution with Q degrees of freedom resive weight zero.
- X: The training data set (same as the input parameter x of the constructor function)
- grp: Grouping variable: a factor specifying the class for each observation (same as the input parameter grouping)

Extends

Class "SosDisc", directly.

Methods

No methods defined with class "SosDiscClassic" in the signature.

Examples

showClass("SosDiscClassic")

36 SosDiscRobust

SosDiscRobust	Robust and sparse multigroup classification by the optimal scoring approach

Description

Robust and sparse multigroup classification by the optimal scoring approach is robust against outliers, provides a low-dimensional and sparse representation of the predictors and is also applicable if the number of variables exeeds the number of observations.

Usage

```
SosDiscRobust(x, ...)
## Default S3 method:
SosDiscRobust(x, grouping, prior=proportions,
    lambda, Q=length(unique(grouping))-1, alpha=0.5, maxit=100,
    tol = 1.0e-4, trace=FALSE, ...)
## S3 method for class 'formula'
SosDiscRobust(formula, data = NULL, ..., subset, na.action)
```

Arguments

formula	A formula of the form y^x , it describes the response and the predictors. The formula can be more complicated, such as $y^log(x)+z$ etc (see formula for more details). The response should be a factor representing the response variable, or any vector that can be coerced to such (such as a logical variable).
data	An optional data frame (or similar: see model.frame) containing the variables in the formula formula.
subset	An optional vector used to select rows (observations) of the data matrix x.
na.action	A function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The default is na.omit.
X	A matrix or data frame containing the explanatory variables (training set); colnames of x have to be provided.
grouping	Grouping variable: a factor specifying the class for each observation.
prior	Prior probabilities, a vector of positive numbers that sum up to 1; default to the class proportions for the training set.
lambda	A non-negative tuning parameter for L1 norm penalty introducing sparsity on the optimal scoring coefficients β_h (see Details). If the number of variables exceeds the number of observations lambda has to be positive.
Q	Number of optimal scoring coefficient vectors; Q has to be smaller than the number of groups. Defaults to number of groups - 1.
alpha	Robustness parameter used in sparseLTS (for initial estimation, see Details). Default alpha=0.5.

SosDiscRobust 37

maxit	Number of iterations for the estimation of optimal scoring coefficients and case weights. Default maxit=100.
tol	Tolerance for convergence of the normed weighted change in the residual sum of squares for the estiamtion of optimal scoring coefficients. Default is tol=1.0e-4.
trace	Whether to print intermediate results. Default is trace = FALSE.
	Arguments passed to or from other methods.

Details

The sparse optimal scoring problem (Clemmensen et al, 2011): for h = 1, ..., Q

$$\min_{\beta_h, \theta_h} \frac{1}{n} ||Y\theta_h - X\beta_h||_2^2 + \lambda ||\beta_h||_1$$

subject to

$$\frac{1}{n} \theta_h^T Y^T Y \theta_h = 1, \quad \theta_h^T Y^T Y \theta_l = 0 \quad \forall l < h,$$

where X deontes the robustly centered and scaled input matrix x (or alternatively the predictors from formular) and Y is an dummy matrix coding die classmemberships from grouping.

For each h this problem can be solved interatively for β_h and θ_h . In order to obtain robust estimates, β_h is estimated with reweighted sparse least trimmed squares regression (Alfons et al, 2013) and θ_h with least absolut deviation regression in the first two iterations. To speed up the following repetitions an iterative down-weighting of observations with large residuals is combined with the iterative estimation of the optimal scoring coefficients with their classical estimates.

The classification model is estimated on the low dimensional sparse subspace $X[\beta_1,...,\beta_Q]$ with robust LDA (Linda).

Value

An S4 object of class SosDiscRobust-class which is a subclass of of the virtual class SosDisc-class.

SosDiscRobust-class

Class SosDiscRobust - robust and sparse multigroup classification by the optimal scoring approach

Description

Robust and sparse multigroup classification by the optimal scoring approach.

SosDiscRobust-class 39

Objects from the Class

Objects can be created by calls of the form new("SosDiscRobust", ...) but the usual way of creating SosDiscRobust objects is a call to the function SosDiscRobust() which serves as a constructor.

Slots

call: The (matched) function call.

prior: Prior probabilities; same as input parameter.

counts: Number of observations in each class.

beta: Object of class "matrix": Q coefficient vectors of the predictor matrix from optimal scoring (see Details); rows corespond to variables listed in varnames.

theta: Object of class "matrix": Q coefficient vectors of the dummy matrix for class coding from optimal scoring (see Details).

lambda: Non-negative tuning paramer from L1 norm penaly; same as input parameter

varnames: Character vector: Names of included predictor variables (variables where at least one beta coefficient is non-zero).

center: Centering vector of the input predictors (coordinate wise median).

scale: Scaling vector of the input predictors (mad).

fit: Object of class "Linda": Linda model (robust LDA model) estimated in the low dimensional subspace $X[\beta_1,...,\beta_Q]$ (see Details)

mahadist2: These will go later to Linda object: squared robust Mahalanobis distance (calculated with estimates from Linda, with common covariance structure of all groups) of each observation to its group center in the low dimensional subspace $X[\beta_1,...,\beta_Q]$ (see Details).

wlinda: These will go later to Linda object: 0-1 weights derived from mahadist2; observations where the squred robust Mahalanobis distance is larger than the 0.975 quantile of the chi-square distribution with Q degrees of freedom resive weight zero.

X: The training data set (same as the input parameter x of the constructor function)

grp: Grouping variable: a factor specifying the class for each observation (same as the input parameter grouping)

Extends

Class "SosDisc", directly.

Methods

No methods defined with class "SosDiscRobust" in the signature.

40 SPcaGrid

References

Clemmensen L, Hastie T, Witten D & Ersboll B (2012), Sparse discriminant analysis. *Technometrics*, **53**(4), 406–413.

Ortner I, Filzmoser P & Croux C (2020), Robust and sparse multigroup classification by the optimal scoring approach. Data Mining and Knowledge Discovery **34**, 723–741. doi: 10.1007/s10618019-006668.

Examples

```
showClass("SosDiscRobust")
```

SPcaGrid

Sparse Robust Principal Components based on Projection Pursuit (PP): GRID search Algorithm

Description

Computes an approximation of the PP-estimators for sparse and robust PCA using the grid search algorithm in the plane.

Usage

```
SPcaGrid(x, ...)
## Default S3 method:
SPcaGrid(x, k = 0, kmax = ncol(x), method = c ("mad", "sd", "qn", "Qn"),
    lambda = 1, scale=FALSE, na.action = na.fail, trace=FALSE, ...)
## S3 method for class 'formula'
SPcaGrid(formula, data = NULL, subset, na.action, ...)
```

Arguments

formula	a formula with no response variable, referring only to numeric variables.
data	an optional data frame (or similar: see model.frame) containing the variables in the formula formula.
subset	an optional vector used to select rows (observations) of the data matrix x.
na.action	a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The default is na.omit.
	arguments passed to or from other methods.
X	a numeric matrix (or data frame) which provides the data for the principal components analysis.
k	number of principal components to compute. If k is missing, or k = 0, the algorithm itself will determine the number of components by finding such k that $l_k/l_1>=10.E-3$ and $\Sigma_{j=1}^k l_j/\Sigma_{j=1}^r l_j>=0.8$. It is preferable to investigate the scree plot in order to choose the number of components and then run again. Default is k=0.

SPcaGrid 41

kmax	is provided, kmax does not need to be specified, unless k is larger than 10.
method	the scale estimator used to detect the direction with the largest variance. Possible values are "sd", "mad" and "Qn". "mad" is the default value.
lambda	the sparseness constraint's strength(sPCAgrid only). A single value for all components, or a vector of length k with different values for each component can be specified. See opt.TPO for the choice of this argument.
scale	a value indicating whether and how the variables should be scaled. If scale = FALSE (default) or scale = NULL no scaling is performed (a vector of 1s is returned in the scale slot). If scale = TRUE the data are scaled to have unit variance. Alternatively it can be a function like sd or mad or a vector of length equal the number of columns of x. The value is passed to the underlying function and the result returned is stored in the scale slot. Default is scale = FALSE
trace	whether to print intermediate results. Default is trace = FALSE

Details

SPcaGrid, serving as a constructor for objects of class SPcaGrid-class is a generic function with "formula" and "default" methods. For details see sPCAgrid and the relevant references.

Value

An S4 object of class SPcaGrid-class which is a subclass of PcaGrid-class which in turn is a subclass of the virtual class PcaRobust-class.
