

# Package ‘topr’

January 13, 2023

**Title** Create Custom Plots for Viewing Genetic Association Results

**Version** 1.1.2

**URL** <https://github.com/GenuityScience/topr>

**BugReports** <https://github.com/GenuityScience/topr/issues>

**Description** A collection of functions for visualizing, exploring and annotating genetic association results. Association results from multiple traits can be viewed simultaneously along with gene annotation, over the entire genome (Manhattan plot) or in the more detailed regional view.

**License** LGPL (>= 3)

**Encoding** UTF-8

**LazyData** true

**LazyDataCompression** xz

**RoxxygenNote** 7.2.0

**Suggests** testthat (>= 3.0.0), knitr, rmarkdown, markdown

**Config/testthat.edition** 3

**Imports** ggplot2 (>= 3.3.2), dplyr (>= 1.0.2), stringr (>= 1.4.0), scales (>= 1.1.1), ggrepel, egg, grid, gridExtra, magrittr (>= 1.5), utils, tidyverse, toprdata

**Depends** R (>= 3.5.0)

**NeedsCompilation** no

**Author** Genuity Science [cph],  
Thorhildur Juliusdottir [aut, cre],  
Andri Stefansson [aut]

**Maintainer** Thorhildur Juliusdottir <[thorhildur@genuitysci.com](mailto:thorhildur@genuitysci.com)>

**Repository** CRAN

**Date/Publication** 2023-01-13 16:20:02 UTC

### annotate\_with\_nearest\_gene

*Get the nearest gene for one or more snps*

## Description

`annotate_with_nearest_gene()` Annotate the variant/snp with their nearest gene Required parameters is a dataframe of SNPs (with the columns CHROM and POS)

## Usage

```
annotate_with_nearest_gene(variants, protein_coding_only = FALSE, build = 38)
```

## Arguments

**variants** a dataframe of variant positions (CHROM and POS)  
**protein\_coding\_only** Logical, if set to TRUE only annotate with protein coding genes (the default value is FALSE)  
**build** A number representing the genome build. Set to 37 to change to build (GRCh37). The default is build 38 (GRCh38).

## Value

the input dataframe with Gene\_Symbol as an additional column

## Examples

```
## Not run:  
variants <-get_lead_snps(CD_UKBB)  
annotate_with_nearest_gene(variants)  
  
## End(Not run)
```

CD\_FINNGEN

*Finngen r7 Crohn's disease (K11\_CROHNS)*

## Description

Dataset retrieved from the Finngen database (version 7) including 3147 crohn's cases (K50) and 296,100 controls. The dataset has been filtered on variants with  $P < 1e-03$ . FinnGen data are publicly available and were downloaded from <https://finngen.fi>.

## Usage

CD\_FINNGEN

## Format

A data frame with 41,095 rows and 8 variables:

**CHROM** Chromosome, written as for example chr1 or 1

**POS** genetic position of the variant

**REF** the reference allele

**ALT** the alternative allele

**P** P-value from Plink run, additive model, regression model GLM\_FIRTH

**BETA** Variant effect

**ID** Variant identifier, e.g. rsid

**AF** Allele frequency

**Source**

Crohn's K50 (K11\_CROHNS), only including variants with P<1e-03

---

CD\_UKBB

*UKBB Crohns disease (ICD 10 code K50)*

---

**Description**

Dataset retrieved from the UK biobank consisting of 2,799 crohn's cases (K50) and 484,515 controls. The dataset has been filtered on variants with P <1e-03.

**Usage**

CD\_UKBB

**Format**

A data frame with 26,824 rows and 8 variables:

**CHROM** Chromosome, written as for example chr1 or 1

**POS** genetic position of the variant

**REF** the reference allele

**ALT** the alternative allele

**ID** Variant identifier, e.g. rsid

**P** P-value from Plink run, additive model, regression model GLM\_FIRTH

**OR** Odds Ratio

**AF** Allele frequency

**Source**

Crohn's UKBB ICD10 code K50, only including variants with P<1e-03

---

create.snpset	<i>Create a dataframe that can be used as input for making effect plots</i>
---------------	---

---

## Description

```
create.snpset()
```

This method is deprecated and will be removed in future versions. use [get.snpset](#) instead.

## Usage

```
create.snpset(  
  df1,  
  df2,  
  thresh = 1e-08,  
  protein_coding_only = TRUE,  
  region_size = 1e+06,  
  verbose = F  
)
```

## Arguments

df1	The dataframe to extract the top snps from (with p-value below thresh)
df2	The dataframe in which to search for overlapping SNPs from dataframe1
thresh	Numeric, the p-value threshold used for extracting the top snps from dataset 1
protein_coding_only	Logical, set this variable to TRUE to only use protein_coding genes for the annotation
region_size	Integer, the size of the interval which to extract the top snps from
verbose	Logical, (default: FALSE). Assign to TRUE to get information on which alleles are matched and which are not.

## Value

Dataframe containing the top hit

## Examples

```
## Not run:  
create.snpset(CD_UKBB,CD_FINNGEN, thresh=1e-09)  
  
## End(Not run)
```

`create.snpset_code`     *Show the code/functions used to create a snpset*

### Description

This method is deprecated and will be removed in future versions. use [get.snpset\\_code](#) instead.  
`create.snpset_code()`

### Usage

```
create.snpset_code()
```

### Value

Dataframe containing the top hit

### Examples

```
## Not run:  
create.snpset_code()  
  
## End(Not run)
```

`effectplot`     *Create a plot comparing variant effects in two datasets*

### Description

```
effectplot()
```

### Usage

```
effectplot(  
  df,  
  pheno_x = "x_pheno",  
  pheno_y = "y_pheno",  
  annotate_with = "Gene_Symbol",  
  thresh = 1e-08,  
  ci_thresh = 1,  
  gene_label_thresh = 1e-08,  
  color = get_topr_colors()[1],  
  scale = 1,  
  build = 38,  
  label_fontface = "italic",  
  label_family = "",
```

```

nudge_y = 0.001,
nudge_x = 0.001,
size = 2,
segment.size = 0.2,
segment.linetype = "solid",
segment.color = "transparent",
angle = 0,
title = NULL,
axis_text_size = 10,
axis_title_size = 12,
title_text_size = 13,
subtitle_text_size = 11,
gene_label_size = 3.2,
snpset_thresh = 1e-08,
snpset_region_size = 1e+06,
max.overlaps = 10,
annotate = 0,
label_color = NULL
)

```

## Arguments

df	The input dataframe (snpset) containing one row per variant and P values (P1 and P2) and effects (E1 and E2) from two datasets/phenotypes OR a list containing two datasets.
pheno_x	A string representing the name of the phenotype whose effect is plotted on the x axis
pheno_y	A string representing the name of the phenotype whose effect is plotted on the y axis
annotate_with	A string, The name of the column that contains the label for the datapoints (default value is Gene_Symbol)
thresh	A number. Threshold cutoff, datapoints with P2 below this threshold are shown as filled circles whereas datapoints with P2 above this threshold are shown as open circles
ci_thresh	A number. Show the confidence intervals if the P-value is below this threshold
gene_label_thresh	Deprecated: A number, label datapoints with P2 below this threshold
color	A string, default value is the first of the top colors
scale	A number, to change the size of the title and axes labels and ticks at the same time (default = 1)
build	A number representing the genome build. Set to 37 to change to build (GRCh37). The default is build 38 (GRCh38).
label_fontface	A string or a vector of strings. Label font “plain”, “bold”, “italic”, “bold.italic” (ggrepel argument)
label_family	A string or a vector of strings. Label font name (default ggrepel argument is "")

<code>nudge_y</code>	A number to horizontally adjust the starting position of each gene label (this is a ggrepel parameter)
<code>nudge_x</code>	A number to vertically adjust the starting position of each gene label (this is a ggrepel parameter)
<code>size</code>	A number or a vector of numbers, setting the size of the plot points (default: <code>size=1.2</code> )
<code>segment.size</code>	line segment color (ggrepel argument)
<code>segment.linetype</code>	line segment solid, dashed, etc.(ggrepel argument)
<code>segment.color</code>	line segment thickness (ggrepel argument)
<code>angle</code>	A number, the angle of the text label
<code>title</code>	A string to set the plot title
<code>axis_text_size</code>	A number, size of the x and y axes tick labels (default: 12)
<code>axis_title_size</code>	A number, size of the x and y title labels (default: 12)
<code>title_text_size</code>	A number, size of the plot title (default: 13)
<code>subtitle_text_size</code>	A number setting the text size of the subtitle (default: 11)
<code>gene_label_size</code>	A number setting the size of the gene labels shown at the bottom of the plot
<code>snpset_thresh</code>	A number representing the threshold used to create the snpset used for plotting (Only applicable if the input dataframe is a list containing two datasets)
<code>snpset_region_size</code>	A number representing the region size to use when creating the snpset used for plotting (Only applicable if the input dataframe is a list containing two datasets)
<code>max.overlaps</code>	Exclude text labels that overlap too many things. Defaults to 10 (ggrepel argument)
<code>annotate</code>	A number, label datapoints with p-value below below this number (in the second df) by their nearest gene
<code>label_color</code>	A string or a vector of strings. To change the color of the gene or variant labels

### Value

ggplot object

### Examples

```
## Not run:
effectplot(list(CD_UKBB, CD_FINNGEN))

## End(Not run)
```

---

**effect\_plot***Create a plot comparing effects within two datasets*

---

**Description**`effect_plot()`

This method is deprecated and will be removed in future versions. use [effectplot](#) instead.

**Usage**

```
effect_plot(  
    dat,  
    pheno_x = "pheno_x",  
    pheno_y = "pheno_",  
    annotate_with = "Gene_Symbol",  
    thresh = 1e-08,  
    ci_thresh = 1,  
    gene_label_thresh = 1e-08,  
    color = get_topr_colors()[1],  
    scale = 1  
)
```

**Arguments**

<code>dat</code>	The input dataframe (snps) containing one row per variant and P values (P1 and P2) and effects (E1 and E2) from two datasets/phenotypes
<code>pheno_x</code>	A string representing the name of the phenotype whose effect is plotted on the x axis
<code>pheno_y</code>	A string representing the name of the phenotype whose effect is plotted on the y axis
<code>annotate_with</code>	A string, The name of the column that contains the label for the datapoints (default value is Gene_Symbol)
<code>thresh</code>	A number. Threshold cutoff, datapoints with P2 below this threshold are shown as filled circles whereas datapoints with P2 above this threshold are shown as open circles
<code>ci_thresh</code>	A number. Show the confidence intervals if the P-value is below this threshold
<code>gene_label_thresh</code>	A string, label datapoints with P2 below this threshold
<code>color</code>	A string, default value is the first of the top colors
<code>scale</code>	A number, to change the size of the title and axes labels and ticks at the same time (default = 1)

**Examples**

```
## Not run:
effect_plot(dat)

## End(Not run)
```

**flip\_to\_positive\_allele\_for\_dat1**  
*Flip to the positive allele for dataset 1*

**Description**

`flip_to_positive_allele_for_dat1()`

**Usage**

`flip_to_positive_allele_for_dat1(df)`

**Arguments**

<code>df</code>	A dataframe that is in the.snpset format (like returned by the <code>get.snpset()</code> function)
-----------------	--

**Value**

The input dataframe after flipping to the positive effect allele in dataframe 1

**Examples**

```
## Not run:
CD_UKBB_index_snps <- get_lead_snps(CD_UKBB)
snpset <- get.snpset(CD_UKBB_index_snps, CD_FINNGEN)
flip_to_positive_allele_for_dat1(snpset$matched)

## End(Not run)
```

---

get\_best\_snp\_per\_MB     *Get the index/lead variants*

---

## Description

`get_best_snp_per_MB()` Get the top variants within 1 MB windows of the genome with association p-values below the given threshold

This method is deprecated and will be removed in future versions. use [get\\_lead\\_snps](#) instead.

## Usage

```
get_best_snp_per_MB(
  df,
  thresh = 5e-09,
  region_size = 1e+06,
  protein_coding_only = FALSE,
  chr = NULL,
  .checked = FALSE,
  verbose = FALSE
)
```

## Arguments

<code>df</code>	Dataframe
<code>thresh</code>	A number. P-value threshold, only extract variants with p-values below this threshold (5e-09 by default)
<code>region_size</code>	An integer (default = 20000000) (or a string represented as 200kb or 2MB) indicating the window size for variant labeling. Increase this number for sparser annotation and decrease for denser annotation.
<code>protein_coding_only</code>	Logical, set this variable to TRUE to only use protein_coding genes for annotation
<code>chr</code>	String, get the top variants from one chromosome only, e.g. <code>chr="chr1"</code>
<code>.checked</code>	Logical, if the input data has already been checked, this can be set to TRUE so it wont be checked again (FALSE by default)
<code>verbose</code>	Logical, set to TRUE to get printed information on number of SNPs extracted

## Value

Dataframe of lead variants. Returns the best variant per MB (by default, change the region size with the `region` argument) with p-values below the input threshold (`thresh=5e-09` by default)

`get_gene`*Get the genetic position of a gene by gene name***Description**`get_gene()` Get the gene coordinates for a gene Required parameter is gene nameThis method is deprecated and will be removed in future versions. use [get\\_gene\\_coords](#) instead.**Usage**`get_gene(gene_name, chr = NULL, build = 38)`**Arguments**

<code>gene_name</code>	A string representing a gene name (e.g. "FTO")
<code>chr</code>	A string, search for the genes on this chromosome only, (e.g <code>chr="chr1"</code> )
<code>build</code>	A string, genome build, choose between builds 37 (GRCh37) and 38 (GRCh38) (default is 38)

**Value**

Dataframe with the gene name and its genetic coordinates

`get_genes_by_Gene_Symbol`*Get the genetic position of a gene by its gene name***Description**`get_genes_by_Gene_Symbol()` Get genes by their gene symbol/name Required parameters is on gene name or a vector of gene names**Usage**`get_genes_by_Gene_Symbol(genes, chr = NULL, build = 38)`**Arguments**

<code>genes</code>	A string or vector of strings representing gene names, (e.g. "FTO") or (c("FTO", "NOD2"))
<code>chr</code>	A string, search for the genes on this chromosome only, (e.g <code>chr="chr1"</code> )
<code>build</code>	A string, genome build, choose between builds 37 (GRCh37) and 38 (GRCh38) (default is 38)

**Value**

Dataframe of genes

**Examples**

```
## Not run:
get_genes_by_Gene_Symbol(c("FTO", "THADA"))

## End(Not run)
```

`get_genes_in_region`    *Get SNPs/variants within region*

**Description**

`get_genes_in_region()`

**Usage**

```
get_genes_in_region(
  chr = chr,
  xmin = xmin,
  xmax = xmax,
  protein_coding_only = F,
  show_exons = F,
  show_genes = T,
  build = 38,
  region = NULL
)
```

**Arguments**

<code>chr</code>	A string, chromosome (e.g. chr16)
<code>xmin</code>	An integer representing genetic position
<code>xmax</code>	An integer representing genetic position
<code>protein_coding_only</code>	A logical scalar, if TRUE, only protein coding genes are used for annotation
<code>show_exons</code>	Deprecated : A logical scalar, show exons instead of genes (default show_exons=FALSE)
<code>show_genes</code>	A logical scalar, show genes instead of exons (default show_genes=FALSE)
<code>build</code>	A number representing the genome build. Set to 37 to change to build (GRCh37). The default is build 38 (GRCh38).
<code>region</code>	A string representing the genetic region (e.g chr16:50693587-50734041)

**Value**

the genes the requested region

**Examples**

```
## Not run:
get_genes_in_region(region="chr16:50593587-50834041")

## End(Not run)
```

---

**get\_gene\_coords**

*Get the genetic position of a gene by gene name*

---

**Description**

`get_gene_coords()` Get the gene coordinates for a gene Required parameter is gene name

**Usage**

```
get_gene_coords(gene_name, chr = NULL, build = 38)
```

**Arguments**

<code>gene_name</code>	A string representing a gene name (e.g. "FTO")
<code>chr</code>	A string, search for the genes on this chromosome only, (e.g <code>chr="chr1"</code> )
<code>build</code>	A string, genome build, choose between builds 37 (GRCh37) and 38 (GRCh38) (default is 38)

**Value**

Dataframe with the gene name and its genetic coordinates

**Examples**

```
## Not run:
get_gene_coords("FTO")

## End(Not run)
```

---

<code>get_lead_snps</code>	<i>Get the index/lead variants</i>
----------------------------	------------------------------------

---

## Description

`get_lead_snps()` Get the top variants within 1 MB windows of the genome with association p-values below the given threshold

## Usage

```
get_lead_snps(
  df,
  thresh = 5e-09,
  region_size = 1e+06,
  protein_coding_only = FALSE,
  chr = NULL,
  .checked = FALSE,
  verbose = NULL,
  keep_chr = TRUE
)
```

## Arguments

<code>df</code>	Dataframe
<code>thresh</code>	A number. P-value threshold, only extract variants with p-values below this threshold (5e-09 by default)
<code>region_size</code>	An integer (default = 20000000) (or a string represented as 200kb or 2MB) indicating the window size for variant labeling. Increase this number for sparser annotation and decrease for denser annotation.
<code>protein_coding_only</code>	Logical, set this variable to TRUE to only use protein_coding genes for annotation
<code>chr</code>	String, get the top variants from one chromosome only, e.g. <code>chr="chr1"</code>
<code>.checked</code>	Logical, if the input data has already been checked, this can be set to TRUE so it wont be checked again (FALSE by default)
<code>verbose</code>	Logical, set to TRUE to get printed information on number of SNPs extracted
<code>keep_chr</code>	Logical, set to FALSE to remove the "chr" prefix before each chromosome if present (TRUE by default)

## Value

Dataframe of lead variants. Returns the best variant per MB (by default, change the region size with the region argument) with p-values below the input threshold (thresh=5e-09 by default)

## Examples

```
## Not run:
get_lead_snps(CD_UKBB)

## End(Not run)
```

`get_overlapping_snps_by_pos`

*Get variants that overlap between two datasets*

## Description

`get_overlapping_snps_by_pos()`

This method is deprecated and will be removed in future versions. use [match\\_by\\_pos](#) instead.

## Usage

```
get_overlapping_snps_by_pos(df1, df2, verbose = F)
```

## Arguments

<code>df1</code>	A dataframe of variants, has to contain CHROM and POS
<code>df2</code>	A dataframe of variants, has to contain CHROM and POS
<code>verbose</code>	A logical scalar (default: FALSE). Assign to TRUE to get information on which alleles are matched and which are not.

## Value

The input dataframe containing only those variants with matched alleles in the snpset

## Examples

```
## Not run:
get_overlapping_snps_by_pos(dat1, dat2)

## End(Not run)
```

---

get.snpset	<i>Create a dataframe that can be used as input for making effect plots</i>
------------	---

---

## Description

get.snpset()

## Usage

```
get.snpset(  
  df1,  
  df2,  
  thresh = 1e-08,  
  protein_coding_only = TRUE,  
  region_size = 1e+06,  
  verbose = NULL,  
  show_full_output = FALSE,  
  build = 38  
)
```

## Arguments

df1	The dataframe to extract the top snps from (with p-value below thresh)
df2	The dataframe in which to search for overlapping SNPs from dataframe1
thresh	A number. P-value threshold, only extract variants with p-values below this threshold (5e-09 by default)
protein_coding_only	Logical, set this variable to TRUE to only use protein_coding genes for annotation
region_size	An integer (default = 20000000) (or a string represented as 200kb or 2MB) indicating the window size for variant labeling. Increase this number for sparser annotation and decrease for denser annotation.
verbose	Logical, (default: FALSE). Assign to TRUE to get information on which alleles are matched and which are not.
show_full_output	A logical scalar (default:FALSE). Assign to TRUE to show the full output from this function
build	A string, genome build, choose between builds 37 (GRCh37) and 38 (GRCh38) (default is 38)

## Value

Dataframe of overlapping snps (snpset)

**Examples**

```
## Not run:
CD_UKBB_index_snps <- get_lead_snps(CD_UKBB)
get.snpset(CD_UKBB_index_snps, CD_FINNGEN)

## End(Not run)
```

**get.snpset\_code** *Show the code/functions used to get a snpset*

**Description**

`get.snpset_code()`

**Usage**

`get.snpset_code()`

**Value**

Dataframe containing the top hit

**Examples**

```
## Not run:
get.snpset_code()

## End(Not run)
```

**get\_snps\_within\_region**

*Get SNPs/variants within region*

**Description**

`get_snps_within_region()`

**Usage**

```
get_snps_within_region(
  df,
  region,
  chr = NULL,
  xmin = NULL,
  xmax = NULL,
  keep_chr = NULL
)
```

**Arguments**

df	data frame of association results with the columns CHR and POS
region	A string representing the genetic region (e.g chr16:50693587-50734041)
chr	A string, chromosome (e.g. chr16)
xmin	An integer, include variants with POS larger than xmin
xmax	An integer, include variants with POS smaller than xmax
keep_chr	Deprecated: Logical, set to FALSE to remove the "chr" prefix before each chromosome if present (TRUE by default)

**Value**

the variants within the requested region

**Examples**

```
## Not run:  
get_snps_within_region(CD_UKBB, "chr16:50593587-50834041")  
  
## End(Not run)
```

---

get\_topr\_colors      *Get the top hit from the dataframe*

---

**Description**

get\_topr\_colors() Get the top hit from the dataframe All other input parameters are optional

**Usage**

```
get_topr_colors()
```

**Value**

Vector of colors used for plotting

**Examples**

```
## Not run:  
get_topr_colors()  
  
## End(Not run)
```

---

<code>get_top_snp</code>	<i>Get the top hit from the dataframe</i>
--------------------------	---

---

## Description

`get_top_snp()` Get the top hit from the dataframe All other input parameters are optional

## Usage

```
get_top_snp(df, chr = NULL)
```

## Arguments

<code>df</code>	Dataframe containing association results
<code>chr</code>	String, get the top hit in the data frame for this chromosome. If chromosome is not provided, the top hit from the entire dataset is returned.

## Value

Dataframe containing the top hit

## Examples

```
## Not run:  
get_top_snp(CD_UKBB, chr="chr1")  
  
## End(Not run)
```

---

<code>locuszoom</code>	<i>Create a locuszoom-like plot</i>
------------------------	-------------------------------------

---

## Description

`locuszoom()` displays the association results for a smaller region within one chromosome. Required parameter is at least one dataset (dataframe) containing the association data (with columns CHROM, POS, P in upper or lowercase)

**Usage**

```
locuszoom(  
  df,  
  annotate = NULL,  
  ntop = 3,  
  xmin = 0,  
  size = 2,  
  shape = 19,  
  alpha = 1,  
  label_size = 4,  
  annotate_with = "ID",  
  color = NULL,  
  axis_text_size = 11,  
  axis_title_size = 12,  
  title_text_size = 13,  
  show_genes = NULL,  
  show_overview = FALSE,  
  show_exons = FALSE,  
  max_genes = 200,  
  sign_thresh = 5e-09,  
  sign_thresh_color = "red",  
  sign_thresh_label_size = 3.5,  
  xmax = NULL,  
  ymin = NULL,  
  ymax = NULL,  
  protein_coding_only = FALSE,  
  region_size = 1e+06,  
  gene_padding = 1e+05,  
  angle = 0,  
  legend_title_size = 12,  
  legend_text_size = 12,  
  nudge_x = 0.01,  
  nudge_y = 0.01,  
  rsids = NULL,  
  variant = NULL,

)

```

## Arguments

<code>df</code>	Dataframe or a list of dataframes (required columns are CHROM, POS, P), in uppercase or lowercase) of association results.
<code>annotate</code>	A number (p-value). Display annotation for variants with p-values below this threshold
<code>ntop</code>	An integer, number of datasets (GWAS results) to show on the top plot
<code>xmin, xmax</code>	Integer, setting the chromosomal range to display on the x-axis
<code>size</code>	A number or a vector of numbers, setting the size of the plot points (default: <code>size=1.2</code> )
<code>shape</code>	A number or a vector of numbers setting the shape of the plotted points
<code>alpha</code>	A number or a vector of numbers setting the transparency of the plotted points
<code>label_size</code>	An number to set the size of the plot labels (default: <code>label_size=3</code> )
<code>annotate_with</code>	A string. Annotate the variants with either Gene_Symbol or ID (default: "Gene_Symbol")
<code>color</code>	A string or a vector of strings, for setting the color of the datapoints on the plot
<code>axis_text_size</code>	A number, size of the x and y axes tick labels (default: 12)
<code>axis_title_size</code>	A number, size of the x and y title labels (default: 12)
<code>title_text_size</code>	A number, size of the plot title (default: 13)

<code>show_genes</code>	A logical scalar, show genes instead of exons (default <code>show_genes=FALSE</code> )
<code>show_overview</code>	A logical scalar, shows/hides the overview plot (default= TRUE)
<code>show_exons</code>	Deprecated : A logical scalar, show exons instead of genes (default <code>show_exons=FALSE</code> )
<code>max_genes</code>	An integer, only label the genes if they are fewer than <code>max_genes</code> (default values is 200).
<code>sign_thresh</code>	A number or vector of numbers, setting the horizontal significance threshold (default: <code>sign_thresh=5.1e-9</code> ). Set to NULL to hide the significance threshold.
<code>sign_thresh_color</code>	A string or vector of strings to set the color/s of the significance threshold/s
<code>sign_thresh_label_size</code>	A number setting the text size of the label for the significance thresholds (default text size is 3.5)
<code>ymin, ymax</code>	Integer, min and max of the y-axis, (default values: <code>ymin=0, ymax=max(-log10(df\$P))</code> )
<code>protein_coding_only</code>	A logical scalar, if TRUE, only protein coding genes are used for annotation
<code>region_size</code>	An integer (default = 20000000) (or a string represented as 200kb or 2MB) indicating the window size for variant labeling. Increase this number for sparser annotation and decrease for denser annotation.
<code>gene_padding</code>	An integer representing size of the region around the gene, if the <code>gene</code> argument was used (default = 100000)
<code>angle</code>	A number, the angle of the text label
<code>legend_title_size</code>	A number, size of the legend title
<code>legend_text_size</code>	A number, size of the legend text
<code>nudge_x</code>	A number to vertically adjust the starting position of each gene label (this is a ggrepel parameter)
<code>nudge_y</code>	A number to horizontally adjust the starting position of each gene label (this is a ggrepel parameter)
<code>rsids</code>	A string ( <code>rsid</code> ) or vector of strings to highlight on the plot, e.g. <code>rsids=c("rs1234, rs45898")</code>
<code>variant</code>	A string representing the variant to zoom in on. Can be either an <code>rsid</code> , or a dataframe (with the columns CHROM,POS,P)
<code>rsids_color</code>	A string, the color of the variants in <code>variants_id</code> (default color is red)
<code>legend_name</code>	A string, use to change the name of the legend (default: None)
<code>legend_position</code>	A string, top,bottom,left or right
<code>chr</code>	A string or integer, the chromosome to plot (i.e. <code>chr15</code> ), only required if the input dataframe contains results from more than one chromosome
<code>vline</code>	A number or vector of numbers to add a vertical line to the plot at a specific chromosomal position, e.g <code>vline=204000066</code> . Multiple values can be provided in a vector, e.g <code>vline=c(204000066, 100500188)</code>

<code>show_gene_names</code>	A logical scalar, if set to TRUE, gene names are shown even though they exceed the max_genes count
<code>legend_labels</code>	A string or vector of strings representing legend labels for the input datasets
<code>gene</code>	A string representing the gene to zoom in on (e.g. gene=FTO)
<code>title</code>	A string to set the plot title
<code>label_color</code>	A string or a vector of strings. To change the color of the gene or variant labels
<code>region</code>	A string representing a genetic region, e.g. chr1:67038906-67359979
<code>scale</code>	A number, to change the size of the title and axes labels and ticks at the same time (default = 1)
<code>rsids_with_vline</code>	A string (rsid) or vector of strings to highlight on the plot with their rsids and vertical lines further highlighting their positions
<code>annotate_with_vline</code>	A number (p-value). Display annotation and vertical lines for variants with p-values below this threshold
<code>sign_thresh_size</code>	A number, sets the size of the horizontal significance threshold line (default = 1)
<code>unit_main</code>	the height unit of the main plot (default = 7)
<code>unit_gene</code>	the height unit of the gene plot (default= 2 )
<code>gene_color</code>	A string representing a color, can be used to change the color of the genes/exons on the geneplot
<code>segment.size</code>	line segment color (ggrepel argument)
<code>segment.color</code>	line segment thickness (ggrepel argument)
<code>segment.linetype</code>	line segment solid, dashed, etc.(ggrepel argument)
<code>show_gene_legend</code>	A logical scalar, set to FALSE to hide the gene legend (default value is TRUE)
<code>max.overlaps</code>	Exclude text labels that overlap too many things. Defaults to 10 (ggrepel argument)
<code>extract_plots</code>	Logical, FALSE by default. Set to TRUE to extract the three plots separately in a list
<code>label_fontface</code>	A string or a vector of strings. Label font “plain”, “bold”, “italic”, “bold.italic” (ggrepel argument)
<code>label_family</code>	A string or a vector of strings. Label font name (default ggrepel argument is "")
<code>gene_label_fontface</code>	Gene label font “plain”, “bold”, “italic”, “bold.italic” (ggrepel argument)
<code>gene_label_family</code>	Gene label font name (default ggrepel argument is "")
<code>build</code>	A number representing the genome build. Set to 37 to change to build (GRCh37). The default is build 38 (GRCh38).
<code>verbose</code>	Logical, set to FALSE to get suppress printed information

show_legend	A logical scalar, set to FALSE to hide the legend (default value is TRUE)
label_alpha	An number or vector of numbers to set the transparency of the plot labels (default: label_alpha=1)
gene_label_size	A number setting the size of the gene labels shown at the bottom of the plot
vline_color	The color of added vertical line/s (default: grey)
vline_linetype	The linetype of added vertical line/s (default : dashed)
vline_alpha	The alpha of added vertical line/s (default : 1)
vline_size	The size of added vertical line/s (default : 0.5)

**Value**

plots using egg (<https://cran.r-project.org/web/packages/egg/vignettes/Ecosystem.html>)

**Examples**

```
## Not run:
locuszoom(R2_CD_UKBB)

## End(Not run)
```

manhattan

*Create a Manhattan plot***Description**

manhattan() displays association results for the entire genome on a Manhattan plot. Required parameter is at least one dataset (dataframe) containing the association data (with columns CHROM, POS, P in upper or lowercase)

All other input parameters are optional

**Usage**

```
manhattan(
  df,
  ntop = 4,
  title = "",
  annotate = NULL,
  color = get_topr_colors(),
  sign_thresh = 5e-09,
  sign_thresh_color = "red",
  sign_thresh_label_size = 3.5,
  label_size = 3.5,
  size = 0.8,
  shape = 19,
  alpha = 1,
```

```
highlight_genes_color = "darkred",
highlight_genes_ypos = 1.5,
axis_text_size = 12,
axis_title_size = 14,
title_text_size = 15,
legend_title_size = 13,
legend_text_size = 12,

)

```

## Arguments

<code>df</code>	Dataframe or a list of dataframes (required columns are CHROM, POS, P), in uppercase or lowercase) of association results.
<code>n_top</code>	An integer, number of datasets (GWAS results) to show on the top plot
<code>title</code>	A string to set the plot title
<code>annotate</code>	A number (p-value). Display annotation for variants with p-values below this threshold
<code>color</code>	A string or a vector of strings, for setting the color of the datapoints on the plot
<code>sign_thresh</code>	A number or vector of numbers, setting the horizontal significance threshold (default: <code>sign_thresh=5.1e-9</code> ). Set to NULL to hide the significance threshold.
<code>sign_thresh_color</code>	A string or vector of strings to set the color/s of the significance threshold/s
<code>sign_thresh_label_size</code>	A number setting the text size of the label for the significance thresholds (default text size is 3.5)
<code>label_size</code>	An number to set the size of the plot labels (default: <code>label_size=3</code> )
<code>size</code>	A number or a vector of numbers, setting the size of the plot points (default: <code>size=1.2</code> )
<code>shape</code>	A number of a vector of numbers setting the shape of the plotted points
<code>alpha</code>	A number or a vector of numbers setting the transparency of the plotted points
<code>highlight_genes_color</code>	A string, color for the highlighted genes (default: darkred)
<code>highlight_genes_ypos</code>	An integer, controlling where on the y-axis the highlighted genes are placed (default value is 1)
<code>axis_text_size</code>	A number, size of the x and y axes tick labels (default: 12)
<code>axis_title_size</code>	A number, size of the x and y title labels (default: 12)
<code>title_text_size</code>	A number, size of the plot title (default: 13)
<code>legend_title_size</code>	A number, size of the legend title
<code>legend_text_size</code>	A number, size of the legend text

<code>protein_coding_only</code>	A logical scalar, if TRUE, only protein coding genes are used for annotation
<code>angle</code>	A number, the angle of the text label
<code>legend_labels</code>	A string or vector of strings representing legend labels for the input datasets
<code>chr</code>	A string or integer, the chromosome to plot (i.e. chr15), only required if the input dataframe contains results from more than one chromosome
<code>annotate_with</code>	A string. Annotate the variants with either Gene_Symbol or ID (default: "Gene_Symbol")
<code>region_size</code>	An integer (default = 20000000) (or a string represented as 200kb or 2MB) indicating the window size for variant labeling. Increase this number for sparser annotation and decrease for denser annotation.
<code>legend_name</code>	A string, use to change the name of the legend (default: None)
<code>legend_position</code>	A string, top,bottom,left or right
<code>nudge_x</code>	A number to vertically adjust the starting position of each gene label (this is a ggrepel parameter)
<code>nudge_y</code>	A number to horizontally adjust the starting position of each gene label (this is a ggrepel parameter)
<code>xmin, xmax</code>	Integer, setting the chromosomal range to display on the x-axis
<code>ymin, ymax</code>	Integer, min and max of the y-axis, (default values: ymin=0, ymax=max(-log10(df\$P)))
<code>highlight_genes</code>	A string or vector of strings, gene or genes to highlight at the bottom of the plot
<code>label_color</code>	A string or a vector of strings. To change the color of the gene or variant labels
<code>legend_nrow</code>	An integer, sets the number of rows allowed for the legend labels
<code>gene_label_size</code>	A number setting the size of the gene labels shown at the bottom of the plot
<code>gene_label_angle</code>	A number setting the angle of the gene label shown at the bottom of the plot (default: 0)
<code>scale</code>	A number, to change the size of the title and axes labels and ticks at the same time (default = 1)
<code>show_legend</code>	A logical scalar, set to FALSE to hide the legend (default value is TRUE)
<code>sign_thresh_linetype</code>	A string, the line-type of the horizontal significance threshold (default = dashed)
<code>sign_thresh_size</code>	A number, sets the size of the horizontal significance threshold line (default = 1)
<code>rsids</code>	A string (rsid) or vector of strings to highlight on the plot, e.g. <code>rsids=c("rs1234, rs45898")</code>
<code>rsids_color</code>	A string, the color of the variants in variants_id (default color is red)
<code>rsids_with_vline</code>	A string (rsid) or vector of strings to highlight on the plot with their rsids and vertical lines further highlighting their positions

annotate_with_vline	A number (p-value). Display annotation and vertical lines for variants with p-values below this threshold
shades_color	The color of the rectangles (shades) representing the different chromosomes on the Manhattan plot
shades_alpha	The transparency (alpha) of the rectangles (shades)
segment.size	line segment color (ggrepel argument)
segment.color	line segment thickness (ggrepel argument)
segment.linetype	line segment solid, dashed, etc.(ggrepel argument)
max.overlaps	Exclude text labels that overlap too many things. Defaults to 10 (ggrepel argument)
label_fontface	A string or a vector of strings. Label font “plain”, “bold”, “italic”, “bold.italic” (ggrepel argument)
label_family	A string or a vector of strings. Label font name (default ggrepel argument is "")
gene_label_fontface	Gene label font “plain”, “bold”, “italic”, “bold.italic” (ggrepel argument)
gene_label_family	Gene label font name (default ggrepel argument is "")
build	A number representing the genome build. Set to 37 to change to build (GRCh37). The default is build 38 (GRCh38).
verbose	A logical scalar (default: NULL). Set to FALSE to suppress printed messages
label_alpha	An number or vector of numbers to set the transparency of the plot labels (default: label_alpha=1)
shades_line_alpha	The transparency (alpha) of the lines around the rectangles (shades)
vline	A number or vector of numbers to add a vertical line to the plot at a specific chromosomal position, e.g vline=chr1:204000066. Multiple values can be provided in a vector, e.g vline=c(chr1:204000066, chr5:100500188)
vline_color	The color of added vertical line/s (default: grey)
vline_linetype	The linetype of added vertical line/s (default : dashed)
vline_alpha	The alpha of added vertical line/s (default : 1)
vline_size	The size of added vertical line/s (default : 0.5)
region	A string representing a genetic region, e.g. chr1:67038906-67359979
theme_grey	Use gray rectangles (instead of white to distinguish between chromosomes)

## Value

ggplot object

## Examples

```
## Not run:
manhattan(CD_UKBB)

## End(Not run)
```

`match_alleles`      *Match the variants in the snpset by their alleles*

## Description

`match_alleles()`

This method is deprecated and will be removed in future versions. use [match\\_by\\_alleles](#) instead.

## Usage

```
match_alleles(df, verbose = F)
```

## Arguments

<code>df</code>	A datafram that is in the snpset format (like returned by the <code>get_snpset()</code> function)
<code>verbose</code>	A logical scalar (default: FALSE). Assign to TRUE to get information on which alleles are matched and which are not.

## Value

The input datafram containing only those variants whith matched alleles in the snpset

## Examples

```
## Not run:  
match_alleles(df)  
  
## End(Not run)
```

`match_by_alleles`      *Match the variants in the snpset by their alleles*

## Description

`match_by_alleles()`

## Usage

```
match_by_alleles(df, verbose = NULL, show_full_output = FALSE)
```

**Arguments**

df	A dataframe that is in the.snpset format (like returned by the <a href="#">get.snpset</a> function)
verbose	A logical scalar (default: FALSE). Assign to TRUE to get information on which alleles are matched and which are not.
show_full_output	A logical scalar (default:FALSE). Assign to TRUE to show the full output from this function

**Value**

The input dataframe containing only those variants with matched alleles in the.snpset

**Examples**

```
## Not run:
CD_UKBB_lead_snps <- get_lead_snps(CD_UKBB)
snps <- get.snpset(CD_UKBB_lead_snps, CD_FINNGEN)
match_by_alleles(snps$found)

## End(Not run)
```

match\_by\_pos

*Get variants that overlap between two datasets*

**Description**

`match_by_pos()`

**Usage**

```
match_by_pos(df1, df2, verbose = NULL, show_full_output = FALSE)
```

**Arguments**

df1	A dataframe of variants, has to contain CHROM and POS
df2	A dataframe of variants, has to contain CHROM and POS
verbose	A logical scalar (default: FALSE). Assign to TRUE to get information on which alleles are matched and which are not.
show_full_output	A logical scalar (default:FALSE). Assign to TRUE to show the full output from this function

**Value**

A list containing two dataframes, one of overlapping snps and the other snps not found in the second input dataset

## Examples

```
## Not run:
CD_UKBB_index_snps <- get_lead_snps(CD_UKBB)
match_by_pos(CD_UKBB_index_snps, CD_FINNGEN)

## End(Not run)
```

**qqtopr**

*Create a quantile quantile (QQ) plot*

## Description

`qqtopr()` displays QQ plots for association data. Required parameter is at least one dataset (dataframe) containing the association data (with columns CHROM, POS, P

## Usage

```
qqtopr(
  dat,
  scale = 1,
  n_variants = 0,
  breaks = 15,
  title = NULL,
  color = get_topr_colors(),
  size = 1,
  legend_name = "",
  legend_position = "right",
  legend_labels = NULL,
  axis_text_size = 11,
  axis_title_size = 12,
  title_text_size = 13,
  legend_title_size = 12,
  legend_text_size = 12,
  verbose = NULL
)
```

## Arguments

<code>dat</code>	Dataframe or a list of dataframes (required columns is P)) of association results.
<code>scale</code>	An integer, plot elements scale, default: 1
<code>n_variants</code>	An integer, total number of variants used in the study
<code>breaks</code>	A number setting the breaks for the axes
<code>title</code>	A string to set the plot title
<code>color</code>	A string or vector of strings setting the color's for the input datasets

size            A number or a vector of numbers, setting the size of the plot points (default: size=1.2)  
 legend\_name     A string, use to change the name of the legend (default: None)  
 legend\_position  
                   A string, top,bottom,left or right  
 legend\_labels    A string or vector of strings representing legend labels for the input datasets  
 axis\_text\_size   A number, size of the x and y axes tick labels (default: 12)  
 axis\_title\_size  
                   A number, size of the x and y title labels (default: 12)  
 title\_text\_size  
                   A number, size of the plot title (default: 13)  
 legend\_title\_size  
                   A number, size of the legend title  
 legend\_text\_size  
                   A number, size of the legend text  
 verbose          A logical scalar (default: NULL). Set to FALSE to suppress printed messages

### Value

ggplot

### Examples

```

## Not run:
qqtopr(CD_UKBB)

## End(Not run)

```

R2\_CD\_UKBB

*Example dataset including the R2 column for the locuszoom plot function*

### Description

The dataset is a subset of CD\_UKBB and only includes variants above and near the IL23R gene on chromosome 1

### Usage

R2\_CD\_UKBB

## Format

A data frame with 329 rows and 5 variables:

**CHROM** Chromosome, written as for example chr1 or 1

**POS** genetic position of the variant

**ID** Variant identifier, e.g. rsid

**P** P-value from Plink run, additive model, regression model GLM\_FIRTH

**R2** variant correlation ( $r^2$ )

## Source

A subset of the CD\_UKBB dataset

**regionplot**

*Create a regionplot*

## Description

`regionplot()` displays the association results for a smaller genetic regions within one chromosome. Required parameter is at least one dataset (dataframe) containing the association data (with columns CHROM, POS, P in upper or lowercase) and either a variant ID, gene name or the genetic region represented as a chromosome together with start and stop positions (either as a single string or as three separate arguments).

All other input parameters are optional

## Usage

```
regionplot(

    vline_linetype = "dashed",
    vline_alpha = 1,
    vline_size = 0.5
)

```

## Arguments

<code>df</code>	Dataframe or a list of dataframes (required columns are CHROM, POS, P), in uppercase or lowercase) of association results.
<code>ntop</code>	An integer, number of datasets (GWAS results) to show on the top plot
<code>annotate</code>	A number (p-value). Display annotation for variants with p-values below this threshold
<code>xmin, xmax</code>	Integer, setting the chromosomal range to display on the x-axis
<code>size</code>	A number or a vector of numbers, setting the size of the plot points (default: <code>size=1.2</code> )
<code>shape</code>	A number or a vector of numbers setting the shape of the plotted points
<code>alpha</code>	A number or a vector of numbers setting the transparency of the plotted points
<code>label_size</code>	An number to set the size of the plot labels (default: <code>label_size=3</code> )
<code>annotate_with</code>	A string. Annotate the variants with either Gene_Symbol or ID (default: "Gene_Symbol")
<code>color</code>	A string or a vector of strings, for setting the color of the datapoints on the plot
<code>axis_text_size</code>	A number, size of the x and y axes tick labels (default: 12)
<code>axis_title_size</code>	A number, size of the x and y title labels (default: 12)
<code>title_text_size</code>	A number, size of the plot title (default: 13)
<code>show_genes</code>	A logical scalar, show genes instead of exons (default <code>show_genes=FALSE</code> )
<code>show_overview</code>	A logical scalar, shows/hides the overview plot (default= TRUE)
<code>show_exons</code>	Deprecated : A logical scalar, show exons instead of genes (default <code>show_exons=FALSE</code> )
<code>max_genes</code>	An integer, only label the genes if they are fewer than <code>max_genes</code> (default values is 200).
<code>sign_thresh</code>	A number or vector of numbers, setting the horizontal significance threshold (default: <code>sign_thresh=5.1e-9</code> ). Set to NULL to hide the significance threshold.
<code>sign_thresh_color</code>	A string or vector of strings to set the color/s of the significance threshold/s

<b>sign_thresh_label_size</b>	A number setting the text size of the label for the significance thresholds (default text size is 3.5)
<b>ymin, ymax</b>	Integer, min and max of the y-axis, (default values: <code>ymin=0, ymax=max(-log10(df\$P))</code> )
<b>protein_coding_only</b>	A logical scalar, if TRUE, only protein coding genes are used for annotation
<b>region_size</b>	An integer (default = 20000000) (or a string represented as 200kb or 2MB) indicating the window size for variant labeling. Increase this number for sparser annotation and decrease for denser annotation.
<b>gene_padding</b>	An integer representing size of the region around the gene, if the gene argument was used (default = 100000)
<b>angle</b>	A number, the angle of the text label
<b>legend_title_size</b>	A number, size of the legend title
<b>legend_text_size</b>	A number, size of the legend text
<b>nudge_x</b>	A number to vertically adjust the starting position of each gene label (this is a ggrepel parameter)
<b>nudge_y</b>	A number to horizontally adjust the starting position of each gene label (this is a ggrepel parameter)
<b>rsids</b>	A string (rsid) or vector of strings to highlight on the plot, e.g. <code>rsids=c("rs1234, rs45898")</code>
<b>variant</b>	A string representing the variant to zoom in on. Can be either an rsid, or a dataframe (with the columns CHROM,POS,P)
<b>rsids_color</b>	A string, the color of the variants in variants_id (default color is red)
<b>legend_name</b>	A string, use to change the name of the legend (default: None)
<b>legend_position</b>	A string, top,bottom,left or right
<b>chr</b>	A string or integer, the chromosome to plot (i.e. chr15), only required if the input dataframe contains results from more than one chromosome
<b>vline</b>	A number or vector of numbers to add a vertical line to the plot at a specific chromosomal position, e.g <code>vline=204000066</code> . Multiple values can be provided in a vector, e.g <code>vline=c(204000066,100500188)</code>
<b>show_gene_names</b>	A logical scalar, if set to TRUE, gene names are shown even though they exceed the max_genes count
<b>legend_labels</b>	A string or vector of strings representing legend labels for the input datasets
<b>gene</b>	A string representing the gene to zoom in on (e.g. gene=FTO)
<b>title</b>	A string to set the plot title
<b>label_color</b>	A string or a vector of strings. To change the color of the gene or variant labels
<b>locuszoomplot</b>	A logical scalar set to FALSE. Only set to TRUE by calling the locuszoom function

<b>region</b>	A string representing a genetic region, e.g. chr1:67038906-67359979
<b>legend_nrow</b>	An integer, sets the number of rows allowed for the legend labels
<b>gene_label_size</b>	A number setting the size of the gene labels shown at the bottom of the plot
<b>scale</b>	A number, to change the size of the title and axes labels and ticks at the same time (default = 1)
<b>show_legend</b>	A logical scalar, set to FALSE to hide the legend (default value is TRUE)
<b>sign_thresh_linetype</b>	A string, the line-type of the horizontal significance threshold (default = dashed)
<b>sign_thresh_size</b>	A number, sets the size of the horizontal significance threshold line (default = 1)
<b>rsids_with_vline</b>	A string (rsid) or vector of strings to highlight on the plot with their rsids and vertical lines further highlighting their positions
<b>annotate_with_vline</b>	A number (p-value). Display annotation and vertical lines for variants with p-values below this threshold
<b>show_gene_legend</b>	A logical scalar, set to FALSE to hide the gene legend (default value is TRUE)
<b>unit_main</b>	the height unit of the main plot (default = 7)
<b>unit_gene</b>	the height unit of the gene plot (default= 2 )
<b>unit_overview</b>	the height unit of the overview plot (default = 1.25)
<b>verbose</b>	Logical, set to FALSE to get suppress printed information
<b>gene_color</b>	A string representing a color, can be used to change the color of the genes/exons on the geneplot
<b>segment.size</b>	line segment color (ggrepel argument)
<b>segment.color</b>	line segment thickness (ggrepel argument)
<b>segment.linetype</b>	line segment solid, dashed, etc.(ggrepel argument)
<b>max.overlaps</b>	Exclude text labels that overlap too many things. Defaults to 10 (ggrepel argument)
<b>unit_ratios</b>	A string of three numbers separated by ":", for the overview, main and gene plots height ratios e.g 1.25:7:2
<b>extract_plots</b>	Logical, FALSE by default. Set to TRUE to extract the three plots separately in a list
<b>label_fontface</b>	A string or a vector of strings. Label font “plain”, “bold”, “italic”, “bold.italic” (ggrepel argument)
<b>label_family</b>	A string or a vector of strings. Label font name (default ggrepel argument is "")
<b>gene_label_fontface</b>	Gene label font “plain”, “bold”, “italic”, “bold.italic” (ggrepel argument)
<b>gene_label_family</b>	Gene label font name (default ggrepel argument is "")

build	A number representing the genome build. Set to 37 to change to build (GRCh37). The default is build 38 (GRCh38).
label_alpha	An number or vector of numbers to set the transparency of the plot labels (default: <code>label_alpha=1</code> )
vline_color	The color of added vertical line/s (default: grey)
vline_linetype	The linetype of added vertical line/s (default : dashed)
vline_alpha	The alpha of added vertical line/s (default : 1)
vline_size	The size of added vertical line/s (default : 0.5)

### Value

plots within ggplotGrobs, arranged with `egg::gtable_frame`

### Examples

```
## Not run:  
regionplot(CD_UKBB, gene="IL23R")  
  
## End(Not run)
```

---

topr	<i>topr</i>
------	-------------

---

### Description

A package for viewing and annotating genetic association data

### topr functions

The main plotting functions are:

- `manhattan` to create Manhattan plot of association results
- `regionplot` to create regional plots of association results for smaller genetic regions

### Examples

```
## Not run:  
library(topr)  
# Create a manhattan plot using  
manhattan(CD_UKBB)  
  
# Create a regional plot  
regionplot(CD_UKBB, gene="IL23R")  
  
## End(Not run)
```

---

UC\_UKBB

*UKBB Ulcerative colitis (ICD 10 code K51)*

---

### Description

Dataset retrieved from the UK biobank including of 5,452 UC cases (K51) and 481,862 controls. The dataset has been filtered on variants with P<1e-03.

### Usage

UC\_UKBB

### Format

A data frame with 57,383 rows and 8 variables

**CHROM** Chromosome, written as for example chr1 or 1

**POS** genetic position of the variant

**REF** the reference allele

**ALT** the alternative allele

**ID** Variant identifier, e.g. rsid

**P** P-value from Plink run, additive model, regression model GLM\_FIRTH

**OR** Odds Ratio

**AF** Allele frequency

### Source

Ulcerative Colitis UKBB ICD10 code K51, only including variants with P<1e-03
